CONTENTS IN BRIEF

PREFACE	xxxix
INTRODUCTION	1

PART ONE *THE FOUNDATIONS OF ECONOMICS*

CHAPTER 1. ECONOMICS AND CAPITALISM	15
CHAPTER 2. WEALTH AND ITS ROLE IN HUMAN LIFE	39
CHAPTER 3. NATURAL RESOURCES AND THE ENVIRONMENT	63

PART TWO *THE DIVISION OF LABOR AND CAPITALISM*

CHAPTER 4. THE DIVISION OF LABOR AND PRODUCTION	123
CHAPTER 5. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM I	135
CHAPTER 6. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM II: THE PRICE SYSTEM AND ECONOMIC COORDINATION	172
CHAPTER 7. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM III: PRICE CONTROLS AND ECONOMIC CHAOS	219
CHAPTER 8. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM IV: SOCIALISM, ECONOMIC CHAOS, AND TOTALITARIAN DICTATORSHIP	267
CHAPTER 9. THE INFLUENCE OF THE DIVISION OF LABOR ON THE INSTITUTIONS OF CAPITALISM	296
CHAPTER 10. MONOPOLY VERSUS FREEDOM OF COMPETITION	375
CHAPTER 11. THE DIVISION OF LABOR AND THE CONCEPT OF PRODUCTIVE ACTIVITY	441

PART THREE *THE PROCESS OF ECONOMIC PROGRESS*

CHAPTER 12. MONEY AND SPENDING	503
CHAPTER 13. PRODUCTIONISM, SAY'S LAW, AND UNEMPLOYMENT	542
CHAPTER 14. THE PRODUCTIVITY THEORY OF WAGES	603

CHAPTER 15. AGGREGATE PRODUCTION, AGGREGATE SPENDING, AND THE ROLE OF SAVING IN SPENDING	673
CHAPTER 16. THE NET-CONSUMPTION/NET-INVESTMENT THEORY OF PROFIT AND INTEREST	719
CHAPTER 17. APPLICATIONS OF THE INVARIABLE-MONEY/NET-CONSUMPTION ANALYSIS	809
CHAPTER 18. KEYNESIANISM: A CRITIQUE	863
CHAPTER 19. GOLD VERSUS INFLATION	895

EPILOGUE

CHAPTER 20. TOWARD THE ESTABLISHMENT OF LAISSEZ-FAIRE CAPITALISM	969
A BIBLIOGRAPHY OF WRITINGS IN DEFENSE OF CAPITALISM	991
INDEX	999

CONTENTS

LIST OF FIGURES	xxxv
LIST OF TABLES	xxxvii
PREFACE	xxxix
Notes	1
INTRODUCTION	
1. Procapitalist Economic Thought, Past and Present	1
2. Pseudoeconomic Thought	6
Marshallian Neoclassical Economics: The Monopoly Doctrine and Keynesianism	7
Mathematical Economics	8
3. Overview of This Book	9
Notes	11

PART ONE *THE FOUNDATIONS OF ECONOMICS*

CHAPTER 1. ECONOMICS AND CAPITALISM

PART A. THE NATURE AND IMPORTANCE OF ECONOMICS

1. Economics, the Division of Labor, and the Survival of Material Civilization	15
2. Further Major Applications of Economics	16
Solving Politico-Economic Problems	16
Understanding History	17
Implications for Ethics and Personal Understanding	17
Economics and Business	18
Economics and the Defense of Individual Rights	18

PART B. CAPITALISM

1. The Philosophical Foundations of Capitalism and Economic Activity	19
2. Capitalism and Freedom	21
Freedom and Government	21
Freedom as the Foundation of Security	22

The Indivisibility of Economic and Political Freedom	23
The Rational Versus the Anarchic Concept of Freedom	23
The Decline of Freedom in the United States	26
The Growth of Corruption as the Result of the Decline of Freedom	26
3. Capitalism and the Origin of Economic Institutions	27
4. Capitalism and the Economic History of the United States	28
5. Why Economics and Capitalism Are Controversial	31
The Assault on Economic Activity and Capitalism	31
The Prevailing Prescientific Worldview in the Realm of Economics	32
Economics Versus Unscientific Personal Observations	32
Economics Versus Altruism	33
Economics Versus Irrational Self-Interest	34
Economics Versus Irrationalism	35
6. Economics and Capitalism: Science and Value	36
Notes	37

CHAPTER 2. WEALTH AND ITS ROLE IN HUMAN LIFE

1. Wealth and Goods	39
2. Economics and Wealth	41
3. The Limitless Need and Desire for Wealth	42
Human Reason and the Scope and Perfectibility of Need Satisfaction	43
Progress and Happiness	45
The Objectivity of Economic Progress: A Critique of the Doctrines of Cultural Relativism and Conspicuous Consumption	46
The Objective Value of a Division-of-Labor, Capitalist Society	48
4. The Law of Diminishing Marginal Utility and the Limitless Need for Wealth	49
5. Applications of the Law of Diminishing Marginal Utility	51
Resolution of the Value Paradox	51
Determination of Value by Cost of Production	52
Determination of Consumer Spending Patterns	52
Say's Law	53

6. “Scarcity” and the Transformation of Its Nature Under Capitalism	54
7. Time Preference and the Scarcity of Capital	55
The Foundations of Time Preference	55
The Scarcity of Capital	56
A Word on Capital Accumulation and the Rate of Return	58
Time Preference, Rationality, and Freedom	58
8. Wealth and Labor	58
The Scarcity of Labor and Its Ineradicability	59
Notes	61

CHAPTER 3. NATURAL RESOURCES AND THE ENVIRONMENT

PART A. NATURAL RESOURCES

1. The Limitless Potential of Natural Resources	63
The Energy Crisis	66
2. The Law of Diminishing Returns	67
The Law of Diminishing Returns and the Limitless Potential of Natural Resources	69
Diminishing Returns and the Need for Economic Progress	70
3. Conservationism: A Critique	71

PART B. THE ECOLOGICAL ASSAULT ON ECONOMIC PROGRESS

1. The Hostility to Economic Progress	76
2. The Claims of the Environmental Movement and Its Pathology of Fear and Hatred	76
The Actual Nature of Industrial Civilization	76
The Environmental Movement’s Dread of Industrial Civilization	78
The Toxicity of Environmentalism and the Alleged Intrinsic Value of Nature	80
The Alleged Pollution of Water and Air and Destruction of Species	83
The Alleged Threat from Toxic Chemicals, Including Acid Rain and Ozone Depletion	85
The Dishonesty of the Environmentalists’ Claims	86
The Alleged Threat of “Global Warming”	87
Why Economic Activity Necessarily Tends to Improve the Environment	90
3. The Collectivist Bias of Environmentalism	91
Environmentalism and Irrational Product Liability	95

Environmentalism and the Externalities Doctrine	96
4. The Economic and Philosophic Significance of Environmentalism	98
5. Environmentalism, the Intellectuals, and Socialism	99
6. Environmentalism and Irrationalism	106
The Loss of the Concept of Economic Progress	106
Irrational Skepticism	106
The Destructive Role of Contemporary Education	107
The Cultural Devaluation of Man	112
Notes	115

PART TWO

THE DIVISION OF LABOR AND CAPITALISM

CHAPTER 4. THE DIVISION OF LABOR AND PRODUCTION

1. The Division of Labor and the Productivity of Labor	123
The Multiplication of Knowledge	123
The Benefit from Geniuses	124
Concentration on the Individual's Advantages	125
Geographical Specialization	125
Economies of Learning and Motion	126
The Use of Machinery	127
2. The Division of Labor and Society	128
3. Rebuttal of the Critique of the Division of Labor	129
4. Universal Aspects of Production	130
Notes	133

CHAPTER 5. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM I

PART A. THE NATURE OF THE DEPENDENCIES

1. Dependence of the Division of Labor on Private Ownership of the Means of Production	135
Socialism and Collectivism Versus Economic Planning	136
Capitalist Planning and the Price System	137
2. The Dependence of the Division of Labor on Saving and Capital Accumulation	139

3. The Dependence of the Division of Labor on Exchange and Money	141
4. The Dependence of the Division of Labor on Economic Competition	144
5. The Dependence of the Division of Labor on the Freedom of Economic Inequality	145
Egalitarianism and the Abolition of Cost: The Example of Socialized Medicine	148
Government Intervention, Democracy, and the Destruction of the Individual's Causal Role	150
Summary	150
PART B. ELEMENTS OF PRICE THEORY: DEMAND, SUPPLY, AND COST OF PRODUCTION	
1. The Meaning of Demand and Supply	152
2. The Law of Demand	155
The Concept of Elasticity of Demand	158
Seeming Exceptions to the Law of Demand	161
The Derivation of Supply Curves	162
Limitations of Geometrical Analysis	165
Confusions Between Supply and Cost	167
The Circularity of Contemporary Economics' Concept of Demand	169
Notes	169
CHAPTER 6. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM II: THE PRICE SYSTEM AND ECONOMIC COORDINATION	
PART A. UNIFORMITY PRINCIPLES	
1. The Uniformity-of-Profit Principle and Its Applications	172
Keeping the Various Branches of Industry in Proper Balance	173
The Power of the Consumers to Determine the Relative Size of the Various Industries	174
The Impetus to Continuous Economic Progress	176
Profits and the Repeal of Price Controls	180
The Effect of Business Tax Exemptions and Their Elimination	183
Additional Bases for the Uniformity-of-Profit Principle	183
Permanent Inequalities in the Rate of Profit	185
2. The Tendency Toward a Uniform Price for the Same Good Throughout the World	187
Why the Arab Oil Embargo Would Not Have Been a Threat to a Free Economy	188
Tariffs, Transportation Costs, and the Case for Unilateral Free Trade	190

3. The Tendency Toward Uniform Prices Over Time: The Function of Commodity Speculation	191
Rebuttal of the Charge That the Oil Shortages of the 1970s Were “Manufactured” by the Oil Companies	192
4. The Tendency Toward Uniform Wage Rates for Workers of the Same Degree of Ability	194
Equal Pay for Equal Work: Capitalism Versus Racism	196
5. Prices and Costs of Production	200

PART B. ALLOCATION PRINCIPLES

1. The General Pricing of Goods and Services in Limited Supply	201
2. The Pricing and Distribution of Consumers’ Goods in Limited Supply	202
3. The Pricing and Distribution of Factors of Production in Limited Supply	206
4. The Free Market’s Efficiency in Responding to Economic Change	209
A Rational Response to the Arab Oil Embargo	211
5. The Economic Harmonies of Cost Calculations in a Free Market	212
More on the Response to the Oil Embargo	213
Appendix to Chapter 6: The Myth of “Planned Obsolescence”	214
Notes	217

CHAPTER 7. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM III:
PRICE CONTROLS AND ECONOMIC CHAOS

PART A. PRICE CONTROLS AND SHORTAGES

1. Price Controls and Inflation	219
Price Controls No Remedy for Inflation	219
Inflation Plus Price Controls	220
2. Shortages	221
3. Price Controls and the Reduction of Supply	222
a. The Supply of Goods Produced	222
b. The Supply of Goods in a Local Market	222
The Natural Gas Crisis of 1977	222
The Agricultural Export Crisis of 1972–73	223
Price Controls as a Cause of War	223
c. The Supply of Goods Held in Storage	223
Hoarding and Speculation Not Responsible for Shortages	224

Rebuttal of the Accusation That Producers Withhold Supplies to “Get Their Price”	224
Price Controls and the “Storage” of Natural Resources in the Ground	225
d. The Supply of Particular Types of Labor and Particular Products of a Factor of Production	226
e. Price Controls and the Prohibition of Supply	226
The Destruction of the Utilities and the Other Regulated Industries	227
4. Ignorance and Evasions Concerning Shortages and Price Controls	228
Inflation and the Appearance of High Profits	228
The Destructionist Mentality	230
A Defense of Inventory Repricing	231
The Campaign Against the Profits of the Oil Companies	231
How the U.S. Government, Not the Oil Companies, Caused the Oil Shortage	234
The Conspiracy Theory of Shortages	237
Rebuttal of the Charge That Private Firms “Control” Prices	238
PART B. FURTHER EFFECTS OF PRICE CONTROLS AND SHORTAGES	
1. Consumer Impotence and Hatred Between Buyers and Sellers	239
How Repeal of Rent Controls Would Restore Harmony Between Landlords and Tenants	240
2. The Impetus to Higher Costs	241
The Administrative Chaos of Price Controls	243
3. Chaos in the Personal Distribution of Consumers’ Goods	243
4. Chaos in the Geographical Distribution of Goods Among Local Markets	244
5. Chaos in the Distribution of Factors of Production Among Their Various Uses	245
Hoarding	246
6. Shortages and the Spillover of Demand	247
Why Partial Price Controls Are Contrary to Purpose	247
How Price Controls Actually Raise Prices	248
The Absurdity of the Claim That Price Controls “Save Money”	248
Applications to Rent Controls	249
How Repeal of Our Price Controls on Oil Reduced the Price Received by the Arabs	254
PART C. UNIVERSAL PRICE CONTROLS AND THEIR CONSEQUENCES	
1. The Tendency Toward Universal Price Controls	256

2. Universal Price Controls and Universal Shortages	257
Excess Demand and Controlled Incomes	257
3. The Destruction of Production Through Shortages	258
The Prosperity Delusion of Price Controls: The World War II “Boom”	262
4. Socialism on the Nazi Pattern	263
Notes	264

CHAPTER 8. THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM IV: SOCIALISM, ECONOMIC CHAOS, AND TOTALITARIAN DICTATORSHIP

PART A. THE CHAOS OF SOCIALISM

1. Socialism	267
2. The Essential Economic Identity Between Socialism and Universal Price Controls	267
3. The Myth of Socialist Planning—The Anarchy of Socialist Production	269
The Soviet Quota System	273
Shortages of Labor and Consumers’ Goods Under Socialism	274
4. Further Economic Flaws of Socialism: Monopoly, Stagnation, Exploitation, Progressive Impoverishment	275
5. Socialism’s Last Gasp: The Attempt to Establish a Socialist Price System and Why It Is Impossible	279

PART B. THE TYRANNY OF SOCIALISM

1. The Tyranny of Socialism	282
2. The Necessity of Evil Means to Achieve Socialism	282
3. The Necessity of Terror Under Socialism	283
4. The Necessity of Forced Labor Under Socialism	286
Forced Labor in the Soviet Union	287
The Imposition of Forced Labor in the United States	287
5. Socialism as a System of Aristocratic Privilege and a Court Society	288
6. From Forced Labor to Mass Murder Under Socialism	290
7. From Socialism to Capitalism: How to Privatize Communist Countries	290
Notes	294

CHAPTER 9. THE INFLUENCE OF THE DIVISION OF LABOR ON THE INSTITUTIONS
OF CAPITALISM

PART A. PRIVATE OWNERSHIP OF THE MEANS OF PRODUCTION

1. The General Benefit from Private Ownership of the Means of Production	296
The Benefit of Capital to the Buyers of Products	296
The Benefit of Capital to the Sellers of Labor	298
The Direct Relationship Between the General Benefit from Capital and Respect for the Property Rights of Capitalists	298
2. The Capitalists' Special Benefit from Private Ownership of the Means of Production	300
Implications for Redistributionism	300
Destructive Consequences of Government Ownership	303
Profit Management Versus Bureaucratic Management	304
The "Successful" Nationalizations of Oil Deposits: A Rebuttal	305
3. The General Benefit from the Institution of Inheritance	306
The Destructive Consequences of Inheritance Taxes	307
4. The General Benefit from Reducing Taxes on the "Rich"	308
5. Private Ownership of Land and Land Rent	310
How Private Ownership of Land Reduces Land Rent	313
Land Rent and Environmentalism	316
The Violent Appropriation Doctrine	317
The Demand for Land Reform	319
6. Private Property and Territorial Sovereignty	322
A Defense of Foreign "Exploitation" of Natural Resources	323

PART B. ECONOMIC INEQUALITY

1. Economic Inequality Under Capitalism	326
2. Critique of the Marxian Doctrine on Economic Inequality	330
Economic Inequality and the Law of Diminishing Marginal Utility	332
Economic Inequality and the Normal Curve	336
3. The "Equality of Opportunity" Doctrine: A Critique	337

Education and the Freedom of Opportunity	342
Everyone's Interest in the Freedom of Opportunity	342
PART C. ECONOMIC COMPETITION	
1. The Nature of Economic Competition	343
2. The Short-Run Loss Periods	345
The Enemies of Competition as the True Advocates of the Law of the Jungle	348
3. Economic Competition and Economic Security	348
4. The Law of Comparative Advantage	350
International Competition and Free Labor Markets	351
Comparative Advantage Versus the Infant-Industries Argument	354
How the Less Able Can Outcompete the More Able in a Free Labor Market	355
5. The Pyramid-of-Ability Principle	357
Freedom of Competition and the General Gain from the Existence of Others	357
6. The Population Question	358
Worldwide Free Trade	360
Free Trade and the Economic Superiority of the United States Over Western Europe	361
International Free Trade and Domestic Laissez Faire	361
The Birth Rate	362
7. Free Immigration	362
Refutation of the Arguments Against Free Immigration	363
Free Immigration and International Wage Rates	366
Capital Export	366
8. The Harmony of Interests in the Face of Competition for Limited Money Revenues	367
Notes	371
CHAPTER 10. MONOPOLY VERSUS FREEDOM OF COMPETITION	
1. The Meaning of Freedom and of Freedom of Competition	375
High Capital Requirements as an Indicator of Low Prices and the Intensity of Competition	376
2. The Political Concept of Monopoly and Its Application	376
Monopoly Based on Exclusive Government Franchises	377

Licensing Law Monopoly	378
Tariff Monopoly	380
The Monopolistic Protection of the Inefficient Many Against the Competition of the More Efficient Few	381
Monopoly Based on Minimum-Wage and Prounion Legislation: The Exclusion of the Less Able and the Disadvantaged	382
Government-Owned and Government-Subsidized Enterprises as Monopoly	385
The Antitrust Laws as Promonopoly Legislation	387
Socialism as the Ultimate Form of Monopoly	387
3. Further Implications of the Political Concept of Monopoly: High Costs Rather Than High Profits	387
Patents and Copyrights, Trademarks and Brandnames, Not Monopolies	388
All Monopoly Based on Government Intervention; Significance of Monopoly	389
4. The Economic Concept of Monopoly	389
5. The Alleged Tendency Toward the Formation of a Single Giant Firm Controlling the Entire Economic System: A Rebuttal	392
Incompatibility With the Division of Labor—Socialism as the Only Instance of Unlimited Concentration of Capital	392
Inherent Limits to the Concentration of Capital Under Capitalism	393
Government Intervention as Limiting the Formation of New Firms	394
The Incentives for Uneconomic Mergers Provided by the Tax System	395
In Defense of “Insider Trading”	395
6. Economically Sound Mergers	396
The Trust Movement	397
7. The Predatory-Pricing Doctrine	399
More Than One Firm in an Industry as the Normal Case	402
“Predatory Pricing” in Reverse: The Myth of Japanese “Dumping”	403
The Chain-Store Variant of the Predatory-Pricing Doctrine	403
Contract Pricing	405
The Predatory-Pricing Doctrine and the Inversion of Economic History	406
The Myth of Predation With Respect to Suppliers	406
The Myth of Standard Oil and the South Improvement Company	407

8. Marginal Revenue and the Alleged “Monopolistic Restriction” of Supply	408
Competitors’ and Potential Competitors’ Costs—Ultimately, Legal Freedom of Entry—as Setting the Upper Limit to Prices in a Free Market	411
Ricardo and Böhm-Bawerk on Cost of Production Versus the Elasticity of Demand	414
Pricing Under Patents and Copyrights	417
Contract Pricing and Radical Privatization	420
Private Streets	421
Eminent Domain	421
9. Cartels	423
Cartels and Government Intervention	424
10. “Monopoly” and the Platonic Competition of Contemporary Economics	425
The Doctrine of Pure and Perfect Competition	430
Implications of Marginal-Cost Pricing	432
The Alleged Lack of “Price Competition”	434
11. A Further Word on Cost of Production and Prices	437
Notes	438

CHAPTER 11. THE DIVISION OF LABOR AND THE CONCEPT OF PRODUCTIVE ACTIVITY

PART A. THE ROLE OF MONEYMAKING IN PRODUCTIVE ACTIVITY

1. The Division of Labor and Productive Activity	441
The Doctrine That Only Manual Labor Is Productive	441
2. Productive Activity and Moneymaking	442
Consumptive Production	443
3. Productive Expenditure and Consumption Expenditure	444
4. Capital Goods and Consumers’ Goods	445
Classification of Capital Goods and Consumers’ Goods Not Based on Physical Characteristics	445
Government a Consumer	446
Producers’ Labor and Consumers’ Labor	446
Producers’ Loans and Consumers’ Loans	447
Government Borrowing	447
Capital Goods and Consumers’ Goods Internally Produced; Other Revenues	447

Capital and Wealth	448
Capital Value and Investment	448
Productive Expenditure and Capital Value	450
Common Confusions About Capital Goods	450
Answers to Misconceptions of the Concepts Presented	452
Adam Smith on “Productive and Unproductive Labor”	456
5. Critique of the Concept of Imputed Income	456
6. Critique of the Opportunity-Cost Doctrine	459
PART B. THE PRODUCTIVE ROLE OF BUSINESSMEN AND CAPITALISTS	
1. The Productive Functions of Businessmen and Capitalists	462
Creation of Division of Labor	462
Coordination of the Division of Labor	463
Improvements in the Efficiency of the Division of Labor	464
2. The Productive Role of Financial Markets and Financial Institutions	464
The Specific Productive Role of the Stock Market	466
3. The Productive Role of Retailing and Wholesaling	467
4. The Productive Role of Advertising	471
PART C. BUSINESSMEN AND CAPITALISTS: CLASSICAL ECONOMICS VERSUS THE MARXIAN EXPLOITATION THEORY	
1. The Association Between Classical Economics and the Marxian Exploitation Theory	473
2. Correcting the Errors of Adam Smith: A Classical-Based Critique of the Conceptual Framework of the Exploitation Theory	475
Smith’s Confusion Between Labor and Wage Earning	475
The Conceptual Framework of the Exploitation Theory	476
Smith’s Failure to See the Productive Role of Businessmen and Capitalists and of the Private Ownership of Land	477
The Primacy-of-Wages Doctrine	477
A Rebuttal to Smith and Marx Based on Classical Economics: Profits, Not Wages, as the Original and Primary Form of Income	478
Further Rebuttal: Profits Attributable to the Labor of Businessmen and Capitalists Despite Their Variation With the Size of the Capital Invested	480
A Radical Reinterpretation of “Labor’s Right to the Whole Produce”	482

Implications for the Incomes of “Passive” Capitalists	483
Acceptance of the Conceptual Framework of the Exploitation Theory by Its Critics	484
3. Necessary Revisions in Classical Economics	485
4. The Labor Theory of Value of Classical Economics	486
Harmonization of the Labor Theory of Value With Supply and Demand and the Productive Role of Businessmen and Capitalists	486
Other Classical Doctrines and the Rise in Real Wages	487
Classical Economics’ Limitations on the Labor Theory of Value	487
The Actual Significance of Quantity of Labor in Classical Economics	491
5. The “Iron Law of Wages” of Classical Economics	491
Diminishing Returns and the Malthusian Influence	492
Ricardo’s Reservations	492
Adam Smith’s Mistaken Belief in the Arbitrary Power of Employers Over Wage Rates	493
Ricardo’s Confusions Concerning the “Iron Law of Wages”	494
The Actual Meaning Ricardo Attached to “A Fall in Wages”	495
Classical Economics’ Mistaken Denial of the Ability to Tax Wage Earners	497
6. Marxian Distortions of Classical Economics; The Final Demolition of the Exploitation Theory	497
Notes	498

PART THREE

THE PROCESS OF ECONOMIC PROGRESS

CHAPTER 12. MONEY AND SPENDING

1. The Quantity Theory of Money	503
The Quantity Theory of Money as the Explanation of Rising Prices	505
2. The Origin and Evolution of Money and the Contemporary Monetary System	506
The Potential Spontaneous Remonetization of the Precious Metals	510
The Government and the Banking System	511
3. The Quantity of Money and the Demand for Money	517
Changes in the Quantity of Money as the Cause of Changes in the Demand for Money	519
4. The Demand for Money: A Critique of the “Balance of Payments” Doctrine	526
The Balance of Payments Doctrine and Fiat Money	528

The Balance of Payments Doctrine Under an International Precious Metal Standard	531
Inflation as the Cause of a Gold Outflow	533
Unilateral Free Trade and the Balance of Trade	535
5. Invariable Money	536
Invariable Money and the Velocity of Circulation	537
The Contribution of the Concept of Invariable Money to Economic Theory	538
Notes	540

CHAPTER 13. PRODUCTIONISM, SAY'S LAW, AND UNEMPLOYMENT

PART A. PRODUCTIONISM	542
Productionism Versus the Anti-Economics of Consumptionism	543
1. Depressions and Alleged "Overproduction"	544
2. Machinery and Unemployment	546
3. Alleged Inherent Group Conflicts Over Employment	548
4. Make-Work Schemes and Spread-the-Work Schemes	549
5. War and Government Spending	550
6. Population Growth and Demand	553
7. Imperialism and Foreign Trade	553
8. Parasitism as an Alleged Source of Gain to Its Victims	554
9. Advertising as Allegedly Fraudulent but Economically Beneficial	555
10. Misconception of the Value of Technological Progress	556
11. Increases in Production and Alleged Deflation	558
12. Consumptionism and Socialism	559
PART B. SAY'S (JAMES MILL'S) LAW	
1. Monetary Demand and Real Demand	559
2. The Referents of Say's Law and Its Confirmation by Cases Apparently Contradicting It	561
3. Partial, Relative Overproduction	564
Say's Law and Competition	568
4. Say's Law and the Average Rate of Profit	569
Production and the Fallacy of Composition	573
5. Falling Prices Caused by Increased Production Are Not Deflation	573

The Anticipation of Falling Prices	574
Economic Progress and the Prospective Advantage of Future Investments Over Present Investments	576
Falling Prices and Accumulated Stocks	578
Falling Prices Resulting from a Larger Supply of Labor	579

PART C. UNEMPLOYMENT

1. The Free Market Versus the Causes of Mass Unemployment	580
Full Employment, Profitability, and Real Wages	583
Government Interference	588
2. Unemployment and the 1929 Depression	589
3. Unemployment, the New Deal, and World War II	590
Why Inflation Cannot Achieve Full Employment	591
Inflation Plus Price and Wage Controls	592
World War II as the Cause of Impoverishment in the United States	592
Prosperity Based on the Return of Peace	593
A Rational Full-Employment Policy	594
Appendix to Chapter 13: Inventories and Depressions	594
Inventories and Capital	595
“Excess” Inventories, Malinvestment, and the Deficiency of Inventories	597
Inflation and Credit Expansion as the Cause of Malinvestment in Inventories	598
Why “Excess” Inventories and Monetary Contraction Are Associated	598
Notes	599

CHAPTER 14. THE PRODUCTIVITY THEORY OF WAGES

PART A. THE MARXIAN EXPLOITATION THEORY

1. The Influence of the Exploitation Theory	603
2. Marx’s Distortions of the Labor Theory of Value	604
Implications for Value Added and Income Formation	605
3. Marx’s Version of the Iron Law of Wages	607
The Rate of Exploitation Formula	608
4. Implications of the Exploitation Theory	610

PART B. THE PRODUCTIVITY THEORY OF WAGES

1. The Irrelevance of Worker Need and Employer Greed in the Determination of Wages	613
2. Determination of Real Wages by the Productivity of Labor	618
3. The Foundations of the Productivity of Labor and Real Wages: Capital Accumulation and Its Causes	622
Saving as a Source of Capital Accumulation	622
Technological Progress as a Source of Capital Accumulation	629
The Reciprocal Relationship Between Capital Accumulation and Technological Progress	631
The Economic Degree of Capitalism, the Wage “Share,” and Real Wages	632
Other Factors, Above All Economic Freedom and Respect for Property Rights, as Sources of Capital Accumulation	634
The Undermining of Capital Accumulation and Real Wages by Government Intervention	636
The Nonsacrificial Character of Capital Accumulation Under Capitalism	639
Appendix to Section 3: An Analytical Refinement Concerning the Rate of Economic Progress	641
4. The Productivity Theory of Wages and the Interpretation of Modern Economic History	642
The Cause of Low Wages and Poor Working Conditions in the Past	642
How Real Wages Rose and the Standard of Living Improved	644
5. A Rise in the Productivity of Labor as the Only Possible Cause of a Sustained, Significant Rise in Real Wages	646
The Futility of Raising Money Wage Rates by Means of an Increase in the Quantity of Money or Decrease in the Supply of Labor	646
The Futility of a Rise in the Demand for Labor Coming at the Expense of the Demand for Capital Goods	647
The Futility of Raising the Demand for Labor by Means of Taxation	648
The Limited Scope for Raising Real Wages Through a Rise in the Demand for Labor	650
6. Critique of Labor and Social Legislation	653
Redistributionism	653
Labor Unions	655
Minimum-Wage Laws	659
Maximum-Hours Legislation	660
Child-Labor Legislation	661
Forced Improvements in Working Conditions	662

8. The Productivity Theory of Wages and the Wages-Fund Doctrine	664
9. The Productivity Theory of Wages Versus the Marginal-Productivity Theory of Wages	666
The Productivity Theory of Wages and the Effect of Diminishing Returns	667
Notes	669
CHAPTER 15. AGGREGATE PRODUCTION, AGGREGATE SPENDING, AND THE ROLE OF SAVING IN SPENDING	
Spending Not a Measure of Output	673
Shortcomings of Price Indexes	674
1. Gross National Product and the Issue of “Double Counting”: A Is A Versus A Is $A+$	674
2. The Role of Saving and Productive Expenditure in Aggregate Demand	682
The Demand for A Is the Demand for A	683
The Demand for Consumers’ Goods and the Demand for Factors of Production as Competing Alternatives	685
Compatibility With the Austrian Theory of Value	689
Application to the Critique of the Keynesian Multiplier Doctrine	690
Saving Versus Hoarding	691
Saving as the Source of Most Spending	694
The “Macroeconomic” Dependence of the Consumers on Business	696
Saving as the Source of Increasing Aggregate Demand, Both Real and Monetary	698
Saving as the Source of Rising Consumption	698
3. Aggregate Economic Accounting on an Aristotelian Base	699
The Consumption Illusion of Contemporary National-Income Accounting	700
Gross National Revenue	706
More on the Critique of the Multiplier	707
4. Importance of Recognizing the Separate Demand for Capital Goods for the Theory of Capital Accumulation and the Theory of National Income	709
The Inverse Relationship Between National Income and Economic Progress in an Economy With an Invariable Money	712
Overthrow of the Keynesian Doctrines of the Balanced-Budget Multiplier and the Conservatives’ Dilemma	714
Notes	716

CHAPTER 16. THE NET-CONSUMPTION/NET-INVESTMENT THEORY OF PROFIT AND INTEREST

PART A. THE POSITIVE THEORY

1. The Nature and Problem of Aggregate Profit	719
The Treatment of Interest	720
The Rate of Profit Not Based on Demand and Supply of Capital, but on the Difference Between the Demand for Products and the Demand for Factors of Production	721
Determinants of the Average Rate of Profit in the Economic System Different from Deter- minants of the Rate of Profit of the Individual Company or Industry	721
Critique of the Doctrine That the Interest Rate on Government Bonds Expresses the Pure Rate of Return to Which Risk Premiums Are Added	722
The Path of Explanation: Net Consumption and Net Investment	723
The Problem of Aggregate Profit: Productive Expenditure and the Generation of Equivalent Sales Revenues and Costs	723
2. Net Consumption and the Generation of an Excess of Sales Revenues Over Productive Expenditure	725
Net Consumption: Its Other Sources, Wider Meaning, and Relationship to the Saving of Wage Earners	734
Confirming the Critique of the Exploitation Theory	735
3. The Net-Consumption Theory Further Considered	737
Why Businessmen and Capitalists Cannot Arbitrarily Increase the Rate of Net Consumption and the Rate of Profit	737
The Net-Consumption Rate and the Gravitation of Relative Wealth and Income	737
Accumulated Capital as a Determinant of Net Consumption	739
An Explanation of High Saving Rates Out of High Incomes	741
Net Consumption and Time Preference	743
4. Net Investment as a Determinant of Aggregate Profit and the Average Rate of Profit	744
Net Investment Versus Negative Net Consumption	750
The Prolongation of Net Investment Under an Invariable Money	754
Net Investment as the Result of the Marginal Productivity of Capital Exceeding the Rate of Profit	756
Net Investment as a Self-Limiting Phenomenon	758
Capital Intensification and the Tendency Toward the Disappearance of Net Investment Under an Invariable Money	758
The Process of Capital Intensification	759
5. The Addition to the Rate of Profit Caused by Increases in the Quantity of Money	762

The Impact of Increases in the Quantity of Money on the Net-Investment and Net-Consumption Rates	768
Increases in the Quantity of Money and the Perpetuation of Net Investment	768
The Increase in the Quantity of Commodity Money as an Addition to Aggregate Profit	771
Summary Statement of the Determinants of the Rate of Profit	773
6. Increases in the Real Rate of Profit Dependent on Increases in the Production and Supply of Goods	774
Net Investment Without Increasing Capital Intensiveness	775
Capital-Saving Inventions	776
7. The Inherent Springs to Profitability	778
Wage Rate Rigidities and Blockage of the Springs	784
Capital Intensiveness and the Monetary Component in the Rate of Profit	784
Capital Intensiveness Under Rapid Obsolescence	786
PART B. THE NET-CONSUMPTION/NET-INVESTMENT THEORY AND ALTERNATIVE THEORIES	
1. Exposition and Critique of the Productivity Theory in Its Traditional Form	787
2. Exposition and Critique of the Time-Preference Theory in Its Traditional Form	792
The Contradiction Between Böhm-Bawerk's "First Cause" and the Doctrine of the Purchasing-Power Premiums	794
The Discounting Approach	795
The Disappearance of the Higher Value of Present Goods at the Margin: Böhm-Bawerk's Abandonment of the Time-Preference Theory	797
3. The Classical Basis of the Net-Consumption Theory	797
Appendix to Section 3: Critique of Ricardo's Doctrine of the Falling Rate of Profit	799
4. Other Proponents of the Net-Consumption/Net-Investment Theory	801
Notes	803
CHAPTER 17. APPLICATIONS OF THE INVARIABLE-MONEY/NET-CONSUMPTION ANALYSIS	
1. The Analytical Framework	809
2. Why Capital Accumulation and the Falling Prices Caused by Increased Production Do Not Imply a Falling Rate of Profit	813
Confirmation of Fact That Falling Prices Caused by Increased Production Do Not Constitute Deflation	817
More on the Relationship Between Technological Progress and the Rate of Profit	818
Ricardo's Insights on Capital Accumulation	819

The Rate of Profit and the Demand for Money	820
3. Why Capital Accumulation Does Not Depend on a Continuous Lengthening of the Average Period of Production	820
The Average Period of Production and the Limits to Technological Progress as a Source of Capital Accumulation	824
4. Implications for the Doctrine of Price Premiums in the Rate of Interest	825
5. Implications for the Process of Raising Real Wages	826
6. How the Taxation of Profits Raises the Rate of Profit	826
The Influence of the Monetary System	828
7. How Government Budget Deficits Raise the Rate of Profit	829
The Need to Reduce Government Spending	830
The Government's Responsibility for the Emphasis of Today's Businessmen on Short-Term Results	831
8. Profits, the Balance of Trade, and the Need for Laissez Faire in the United States	831
9. Implications for the Theory of Saving	834
Net Saving and Increases in the Quantity of Money	834
Why the Actual Significance of Saving Lies at the Gross Level	835
Net Saving and the Rate of Profit	836
10. More on Saving and "Hoarding": "Hoarding" as a Long-Run Cause of a Rise in the Rate of Profit	837
Implications for the Critique of Keynesianism	837
11. Critique of the Investment-Opportunity and Underconsumption/Oversaving Doctrines	838
The Basic Error of Underconsumptionism	841
How the Demand for Capital Goods and Labor Can Radically and Permanently Exceed the Demand for Consumers' Goods	843
Consumption as the Purpose of Production and the Progressive Production of Consumers' Goods Over Time	847
The Ratio of Demands Between Stages	851
More on the Average Period of Production	852
A Rise in the Demand for Capital Goods and Fall in the Demand for Consumers' Goods: The Cross-Hatching of Production	854
12. More on Why Savings Cannot Outrun the Uses for Savings	856
Capital Intensiveness and Land Values	856

The Housing Outlet and Consumer Interest	857
The Automatic Adjustment of the Rate of Saving to the Need for Capital	858
Notes	859
CHAPTER 18. KEYNESIANISM: A CRITIQUE	863
1. The Essential Claims of Keynesianism	864
Neo-Keynesianism	865
2. The Unemployment Equilibrium Doctrine and Its Basis: The <i>IS</i> Curve and Its Elements	867
The Grounds for the <i>MEC</i> Doctrine	875
The Keynesian Solution: “Fiscal Policy”	876
3. Critique of the <i>IS-LM</i> Analysis	879
The Declining-Marginal-Efficiency-of-Capital Doctrine and the Fallacy of Context Dropping	879
The Marginal-Efficiency-of-Capital Doctrine and the Claim That the Rate of Profit Is Lower in the Recovery from a Depression Than in the Depression	881
The Unemployment Equilibrium Doctrine and the Claim That Saving and Net Investment Are at Their Maximum Possible Limits at the Very Time They Are Actually Negative	881
The Marginal-Efficiency-of-Capital Doctrine’s Reversal of the Actual Relationship Between Net Investment and the Rate of Profit	882
The Contradiction Between the Marginal-Efficiency-of-Capital Doctrine and the Multiplier Doctrine	883
A Fall in Wage Rates as the Requirement for the Restoration of Net Investment and Profitability Along With Full Employment	883
Wage Rates, Total Wage Payments, and the Rate of Profit	884
Critique of the “Paradox-of-Thrift” Doctrine	884
Critique of the Saving Function	885
Critique of the “Liquidity-Preference” Doctrine	885
4. The Economic Consequences of Keynesianism	887
The Growth in Government	888
Budget Deficits, Inflation, and Deflation	888
Keynesianism and Economic Destruction	889
Why Keynesianism Is Not a Full Employment Policy	890
Keynesianism Versus the Rate of Profit: “The Euthanasia of the Rentier” and “The Socialization of Investment”	891

CHAPTER 19. GOLD VERSUS INFLATION

PART A. INFLATION OF THE MONEY SUPPLY VERSUS ALTERNATIVE THEORIES OF RISING PRICES

1. The Analytical Framework of the Quantity Theory of Money	895
The Vital Demand/Supply Test for All Theories of Rising Prices	897
The Elimination of Less Supply as the Cause of an Inflationary Rise in Prices	897
2. Refutation of the “Cost-Push” Doctrine in General	907
3. Critique of the “Wage-Push” Variant	909
4. Critique of the “Profit-Push” Variant	911
5. Critique of the “Crisis-Push” Variant	913
6. Critique of the Wage-Price Spiral Variant	915
7. Critique of the “Velocity” Doctrine	915
8. Critique of the “Inflation-Psychology” Doctrine	916
9. Critique of the Credit-Card Doctrine	917
10. Critique of the Consumer-Installment-Credit Doctrine	919
11. Critique of the Consumer-Greed Doctrine	920
12. The Meaning of Inflation	920

PART B. THE DEEPER ROOTS AND FURTHER EFFECTS OF INFLATION

1. The Connection Between Inflation and Government Budget Deficits	922
Budget Deficits and the Monetary Unit	924
2. The Motives and Rationale for Deficits and Inflation	925
The Welfare State	925
Inflation and War Finance	926
Inflation and the “Easy Money” Doctrine	926
Inflation as the Alleged Cure for Unemployment	926
The Underlying Influence of the Socialist Ideology	926
3. Inflation and Deficits Versus Representative Government and Economic Freedom	927
4. Inflation as the Cause of a Redistribution of Wealth and Income	928
5. Inflation and the Destruction of Capital	930

Reversal of Safety	930
Tax Effects	931
The Prosperity Delusion and Overconsumption	933
Malinvestment	935
The Withdrawal-of-Wealth Effect	936
6. Consequences of the Destruction of Capital	937
Reduction of the Real Rate of Return	937
The Gains of Debtors Less Than the Losses of Creditors	937
The Impoverishment of Wage Earners	937
The Stock Market and Inflationary Depression	938
7. Inflation as the Cause of Depressions and Deflation	938
Gold Clauses and Prospective Inflation of Paper as the Cause of Deflation in Gold	940
8. Inflation as the Cause of Mass Unemployment	941
9. The Inherent Accelerative Tendencies of Inflation	942
The Welfare-State Mentality	943
Inflation to Solve Problems Caused by Inflation	944
Recessions as Inflationary Fueling Periods	945
Indexing and the Wage and Interest Ratchets	945
The Current State of Inflation	946
Inflation and the Potential Destruction of the Division of Labor	949
PART C. GOLD	
1. Freedom for Gold as the Guarantee Against the Destruction of Money	951
A Proper Gold Policy for the Government	951
2. The Case For a 100-Percent-Reserve Gold Standard	954
Falling Prices Under the 100-Percent-Reserve Gold Standard Would Not Be Deflationary	954
The 100-Percent-Reserve Gold Standard as the Guarantee Against Deflation	955
Further Virtues of the 100-Percent-Reserve Gold Standard	956
The Moral Virtue of the 100-Percent-Reserve Gold Standard	957
The Monetary Role of Silver	958
3. The 100-Percent-Reserve Gold Standard as the Means of Ending Inflation Without a Depression	959

The 100-Percent-Reserve Gold Standard, Liquidity, and the Dismantling of the Welfare State	962
Notes	963

EPILOGUE

CHAPTER 20. TOWARD THE ESTABLISHMENT OF LAISSEZ-FAIRE CAPITALISM

1. Introduction	969
The Importance of Capitalism as a Conscious Goal	969
The Capitalist Society and a Political Program for Achieving It	971
2. Privatization of Property: Importance of Fighting on Basis of Principles	972
3. The Freedom of Production and Trade	973
Appropriate Compromises	974
The Case for the Immediate Sweeping Abolition of All Violations of the Freedom of Production and Trade	974
4. Abolition of the Welfare State	976
Elimination of Social Security/Medicare	976
Elimination of Public Welfare	977
Elimination of Public Hospitals	978
Firing Government Employees and Ending Subsidies to Business	978
Escaping from Rent Control With the Support of Tenants	980
5. Abolition of Income and Inheritance Taxes	980
6. Establishment of Gold as Money	982
7. Procapitalist Foreign Policy	982
Freedom of Immigration	984
Friendly Relations With Japan and Western Europe	985
8. Separation of State from Education, Science, and Religion	986
Abolition of Public Education	986
Separation of Government and Science	986
Separation of State and Church	987
9. A General Campaign at the Local Level	988
10. The Outlook for the Future	989
Notes	990

PREFACE

This book is the product of a labor of love extending over many years. I conceived of it as an explicit project at least as far back as the spring of 1977, when I made a several-page-long list of the major points it would contain. Although I was eager to begin writing it at once, one thing after another interfered, the most important being finding a publisher for my previous book *The Government Against the Economy*, which I had only recently completed. As a result of this and a considerable variety of less important projects, I was not able actually to begin work on the present book until sometime in 1981.

In that year and the next, I completed the first draft of what are now the Introduction and first three chapters.

In 1982, my wife Edith Packer and I, together with our friend Jerry Kirkpatrick, founded what later became known as The Jefferson School of Philosophy, Economics, and Psychology (TJS). I agreed to deliver eight lectures on the institutions and functioning of a capitalist society for TJS's first summer conference, which was held the following year on the campus of the University of California, San Diego. Those lectures, which were fully written out, constituted the first draft of what are now Chapters 4 and 9 and the first part of Chapter 5.

The writing out of my lectures for succeeding TJS summer conferences in 1985, 1987, and 1989, which were also held on the UCSD campus, represented drafts of what are now chapters 11 and 13–17.¹ My 1986 TJS Fall seminar lecture was the first draft of what is now Chapter 20, which bears the same title as the lecture, namely, "Toward the Establishment of a Capitalist Soci-

ety." Thus, this book is a lasting legacy of the TJS conferences and seminars.

By 1990, my progress on the book had decisively outstripped my lecture preparations and I was using material from the manuscript as the substance of my lectures.² By this time, I at last had a complete draft of the book, which included an updated and expanded version of *The Government Against the Economy* as Chapters 6–8. Extensive editing, reorganization, and rewriting occupied another five years, with the result that the work that is offered now is as well organized, well-written, and clear as I have been able to make it.

I want to say that a very important element in the pleasure I have derived from the writing of this book rested on my use of a personal computer. When I wrote *The Government Against the Economy* and when I began writing this book, I experienced it as me, a fountain pen, and a yellow legal pad against the world. I fully believed, of course, that the pen is mightier than the sword and that with my pen I would ultimately prevail. But however mighty is the pen, the personal computer is far mightier. And every morning, since the fall of 1983, when I entered my office and sat down at my desk I would eagerly watch my computer as it went through its startup routine. My thought was, in effect, "Here is this wonderful, extremely powerful machine that is my ally in the work I am doing and that makes the doing of it so much easier and more enjoyable." To me, as a writer, the personal computer is the greatest of all the remarkable goods supplied by capitalism, surpassing even the personal automobile in its contribution to the ease and enjoyment of life. Without

it, the writing of this book would probably not have been possible.

On a vacation early in the course of writing this book, I read a Western novel by the late Louis L'Amour. I don't remember the story itself, but one brief portion of the novel has stood out in my mind ever since and was a significant help to me in the rest of my writing. It was about the journey of pioneers traveling west in covered wagons, and described how on some days they would make so little progress that after a whole day's march, they could still see the remains of their campfires of the night before. The important thing to those pioneers, L'Amour stressed, was that each day they did make *some* progress—they always finished the day further west than they began it. This became an inspiration to me on all those days when the end result of many hours of work was that I had gotten only a few paragraphs beyond where I had finished the night before. At those times, I contented myself with the knowledge that at least I was that many paragraphs further ahead and that I was still moving "west," so to speak. In retrospect, I think of things somewhat more humorously, and say to myself, "Even if you average just half a page a day, after five or ten years it adds up."

I said that I conceived of this book as an explicit project in 1977. It was an implicit project long before that time. It is the culmination of practically a lifetime of concern that I have had for the protection of property rights and for the right of individuals personally and selfishly to enjoy all the prosperity they can peacefully achieve. I remember identifying as a boy of no more than ten or eleven years of age that what the tenants and city government of New York, which is where I then lived, were doing with the property of the landlords of that city, by means of rent control, was exactly the same in principle as what schoolyard bullies often did with my baseball or football—namely, seize it against the will of its owner and arbitrarily use it for their own pleasure, without a thought for the rights of the owner, mine or the landlords'.

From that early age, I was very much aware of a widespread contempt and hostility toward property rights and property owners—a contempt and hostility manifested in such comments as the one I heard a little later from a junior high school teacher that she did not care about the fact that there were people paying ninety percent of their incomes in taxes (which was then the maximum federal surtax rate), "because they still had a lot left." When I encountered the same attitude of contemptuous philosophic indifference to the violation of property rights in one of my own close relatives, I came to the conclusion that property rights were very much in need of defense, and that I must write a book on their

behalf. I actually set out to write such a book at the time, and succeeded in putting together about one or two paragraphs.

It was clear to me that such contemptuous attitudes and the violations of property rights that they supported were contrary to everything that the Declaration of Independence and Constitution of the United States stood for, which above all was the right of the individual to the pursuit of his own happiness, which included his material prosperity and enjoyment of same. Indeed, my first serious professional ambition, which I held around the age of twelve, was to become a Constitutional lawyer, so that I might best defend that right.

I can trace my admiration for the United States' Constitution back to about the age of five. I remember early in World War II, asking my father why the United States deserved to win all the wars it had ever fought, as well as the one it was now in. He answered that the United States was the world's best country. And when I asked what made it the world's best country, he answered "the Constitution." I don't know what understanding I could have had of such an abstraction at that very young age, but I am quite sure that very early, at least implicitly, I grasped that the Constitution was a body of principles controlling the behavior of the government of the United States and defining the character of that government as good. The Constitution, I came very early to understand, made the United States the world's best country because it created a government that, totally unlike the governments of the countries of Europe and the rest of the world, did not harass its citizens, but instead left them free to pursue their happiness. This, I understood, was why both pairs of my grandparents had come to the United States and why all the immigrants, starting with the Pilgrims, had come to America. I wondered why all other countries did not adopt the Constitution of the United States.

Until the age of eleven or twelve, I took for granted that practically every American recognized the value of his country because he loved its freedom and supported the principles on which the United States was based. Based on my reading of editorials and columnists in the Hearst Press, then represented in New York by *The Daily Mirror* and the *Journal American*, I thought that now that the Nazis had been defeated, the only exceptions were a handful of communist or socialist crackpots.

I had had an inkling, at the age of ten, that this sanguine view of things might not be altogether accurate. This occurred when someone pointed out to me that the paper currency of the United States had imprinted on it a promise to pay the bearer on demand the number of dollars on the face of the bill, that until 1933 this had meant a promise to pay those dollars *in gold coin*, which was the money of the country affirmed by the Constitu-

tion, but now meant the utter absurdity of paying the bearer merely the very same kind of paper notes that he already possessed. I was astounded that such an obvious absurdity was tolerated—that it was accepted routinely, everyday, by everyone, without protest.

My cheerful confidence in the popularity of individual freedom did not begin to erode, however, until I reached junior high school. There, after a few months' attendance, I came to the conclusion that a disproportionate number of the communist and socialist crackpots I had read about were to be found among my teachers. In addition to numerous such remarks by teachers as the one I described above, I encountered teachers who openly confessed to being socialists, including one who regretted that he lived just inside the border of a conservative Republican's congressional district because if he lived across the street he could have voted for Representative Vito Marcantonio, then the most far-leftwing member of Congress. The same man described the Soviet Union as a great experiment. He and his colleagues dismissed questions that challenged any of their interpretations by referring to the presumed size of the bank account or stock portfolio of the questioner's father. I clearly remember this man's response to what I thought was an astonishing fact that all by itself proved the value of the United States and what it stood for, a fact which I happily conveyed to my classmates in the seventh grade in an oral report, and which I had learned from a motion-picture documentary shortly before. This was the fact that with only six percent of the world's population, the United States produced fully forty percent of the world's annual output of goods and services. The man's reply was yes, but so what; ten percent of the country's population owned ninety percent of its wealth.

I soon realized that no one I knew, neither other students, nor any of the adults I knew, was able to answer the leftwing arguments I was encountering daily at school. For a time, I thought, the explanation was that this was New York City. The people here have been intellectually corrupted. But the rest of the country is still full of people who support the principles of individual rights and freedom and know how to defend them. Over the next two summers, I learned that the problem was nationwide. I made this discovery as the result of my experiences at a vacation camp in Maine, where I met a wide variety of college students from all over the country who were working as camp counselors, as well as occasional local citizens. The college students too included a goodly proportion of self-confessed "social democrats." I remember one of them telling me with obvious contempt how ignorant the parents of many of the campers were. They had been to see a local production of a play by George Bernard Shaw that made their type of people its targets, and

they all loved it.

There was a flood of leftist arguments against individual rights and freedom, and nowhere were there answers being given, at least nowhere that I had found. I reluctantly came to the conclusion that the principles of individual rights and freedom enshrined in the Declaration of Independence and Constitution had largely lost their influence on the American people and that these glorious documents themselves were on the way to becoming items of merely historical interest, rather than living documents controlling the conduct of our country's government.

It quickly became obvious to me, from the arguments of my teachers and the college students I met, and from those even of my own dentist, who favored socialized medicine, that what gave rise to the contempt for property rights and property owners, and the readiness to discard everything that the United States as a country had stood for in defending those rights, was a set of *economic* beliefs. Respect for property rights, it was held, was tantamount to respecting the right of a handful of capitalist exploiters to impoverish the masses by paying them starvation wages on the one side while charging them outrageous, monopoly prices on the other. Respecting the rights and freedom of businessmen and capitalists, it was claimed, was also the cause of terrible depressions and mass unemployment, as well as the cause of unsafe food and drugs, child labor, sweat shops, poverty in old age, wars, and countless other evils. Again and again, I saw, the assault on property rights was based on ideas about economics. It was ideas about economics that were destroying the concepts of individual rights and freedom. And, thus, by the age of thirteen, I gave up my ambition to become a Constitutional lawyer and began the study of economics instead.

I undertook the study of economics for the explicit purpose of finding economic arguments in defense of individual rights, i.e., property rights. In my first year of study, with the aid of a dictionary by my side, I read substantial portions of Adam Smith's *The Wealth of Nations* and David Ricardo's *Principles of Political Economy and Taxation*, as well as the whole of a book on the history of economic thought. I started with Smith and Ricardo in the belief that their books would provide the arguments I was seeking, for they had the reputation of having been the leading defenders of capitalism in the system's heyday. Although my mature evaluation of them is that they do in fact have some very important things to say in the defense of capitalism, I was greatly disappointed in them at the time, because it seemed to me that with their support for the labor theory of value, they served merely to prepare the ground for Marx.³ None of the other authors described in the book I read on

the history of economic thought appeared to offer any serious arguments in defense of capitalism.

I turned to browsing the card catalog of the public library for any author who might be a defender of capitalism and from whom I might learn something. In my search, I came across *Capitalism, Socialism, and Democracy* by Joseph Schumpeter, and *Capitalism: The Creator* by Carl Snyder, both of which books I quickly gave up on. I considered Schumpeter valueless as soon as I came across his statement that while socialism looked better than capitalism on paper, capitalism had proved superior to socialism in practice. To me this meant that Schumpeter was saying that socialism seemed better as far as we could think and speak about it, but that somehow, for reasons that we could not understand or verbalize, capitalism turned out to be better in the real world. That was not what I was looking for, which was to know why capitalism was right *in theory*, and not just in some realm of practice that could not be understood in theory. I immediately gave up on Snyder for essentially the same reason—namely, his book appeared to be largely descriptive and statistical and to have little or nothing to say in the essential realm of conceptual understanding, i.e., of theory. I experienced great disappointment even in Thomas Jefferson, when I read that he thought that the preservation of an *agricultural* society was essential for liberty. I realized that the modern world depended vitally on such things as steel mills and all other forms of heavy industry, and I wanted authors who would defend individual rights *in that context*.

At the age of fourteen, I discovered William Stanley Jevons's *The State in Relation to Labour* and *The Theory of Political Economy*.⁴ While the first of these titles began with major concessions on the side of government intervention, the substance of the book was a brilliant analysis of the destructive consequences of labor unions.⁵ The second was an exposition of the theory of marginal utility, which I valued greatly, inasmuch as it seemed to provide an essential part of the answer to Marxism—enough, at least, to convince me that Marx and all of my Marxist high-school teachers were wrong in economic theory.

During this period, I had come to subscribe to a fortnightly magazine called *The Freeman*. At that time, Henry Hazlitt played a major role in writing the magazine's editorials and in determining its content. So long as he continued in that role, I found the magazine so valuable that I read every issue from cover to cover.

It was in one of the early issues of *The Freeman* that I had my first exposure to the writings of Ludwig von Mises. It was his essay "Lord Keynes and Say's Law."⁶ From reading the essay, I could see that Mises knew the history of economic thought and that he was presenting

a strong, self-assured position in defense of an important and relatively complicated aspect of the functioning of capitalism, a position that Say and Ricardo had taken in the early nineteenth century, which was that general business depressions could never be caused by any so-called excess of production. I knew immediately that here was a man I must read further. And, a few months later, at the age of fourteen, I borrowed his classic *Socialism* from the public library.⁷ Unfortunately, the book was then beyond me and I was not able to gain very much from the parts I attempted to read. But less than a year later, with some of the money I had been given on my fifteenth birthday, I bought *Socialism* and over the coming months had one of the very greatest intellectual experiences of my life, before or since. In the intervening months since my previous attempt, my mental powers must have grown the intellectual equivalent of the several inches that boys of that age are capable of growing in such a short time, because I was now able to understand a very great deal of what I read. And what I read filled me with a sense of utter enlightenment.

Mises argued that real wages were determined by the productivity of labor, which in turn depended on capital accumulation, which was accomplished by the saving and investment of businessmen and capitalists and was undermined by progressive income and inheritance taxation. He explained the operations of the price system and showed that the businessmen and capitalists were not a law unto themselves but, in order to make profits and avoid losses, had to produce the goods the consumers wanted to buy. He showed how price controls destroyed the price system and resulted in the establishment of de facto socialism, of which Nazi Germany was the leading example. He explained why socialism had to fail economically, because of its lack of markets and consequent inability to have a price system and thus to perform economic calculations. He showed how political freedom depended on economic freedom and thus why socialism, with its utter lack of economic freedom, was necessarily a system of dictatorship. He showed how under capitalism, the privately owned means of production operated to the benefit of the great mass of nonowners of the means of production to almost as great an extent as they did to the benefit of the owners and that economic progress, based on the profit motive and saving and capital accumulation, brought about a steadily rising standard of living of the nonowners. He showed how the law of comparative advantage made room for virtually everyone, however unskilled, to participate in the great world-embracing system of division of labor and to obtain all of its essential benefits. He showed that unemployment and the consequent inability of people to participate in the division of labor was the result of government

interference with the height of wage rates. He showed why the economic interests of all individuals and groups, of all countries, races, and economic classes were fundamentally harmonious and were made to conflict only by means of the adoption of the irrational ideologies of nationalism, racism, and Marxism and the policies of government intervention based upon them. He demonstrated that the existence of society—a division-of-labor society—and of all the other people who participated in it, was in the material self-interest of every individual, and thus that there was a profoundly rational, self-interested basis for social cooperation and such ethical norms as not killing or injuring other people.

These essential points were amplified and additional major arguments were added to them in his other writings then available in English, above all, *Human Action* and *The Theory of Money and Credit*, as well as *Planning For Freedom*, *Bureaucracy*, and *Omnipotent Government*, all of which I read over the next three years. In these other works Mises added vigorous defenses of the gold standard, brilliant analyses of inflation, compelling demonstrations that depressions were the result of government-sponsored credit expansion, and much else besides. Reading Mises on a random day, I would encounter such brilliant observations as that even if a chorus of people were simultaneously to say “We,” it would still be individuals who were saying it, which served as an illustration of the fact that collectives and groups of any kind had no real existence apart from the individuals who comprised them; that high profits provided not only an incentive to stepped-up investment, but also the means of stepped-up investment, inasmuch as the high profits would themselves be largely reinvested; that war and division of labor were incompatible, inasmuch as war represented a situation of the baker fighting the tailor, with the result that both parties were deprived of vital supplies; that democracy was necessary as the means of making possible peaceful changes in government, so that a dissatisfied majority would not have to resort to revolution or civil war to have its way; and so on. Looking back, I do not recall a single paragraph of von Mises that did not serve as an inspiration to my own thinking, even in the cases (which were relatively few) in which I ultimately came to disagree with him.

Mises was clearly the man whose writings I had been searching for. Here at last was a great, articulate defender of the economic institutions of capitalism, who wrote with all the power that logical argument could provide and with the authority of the highest level of scholarship. (*Socialism* and *Human Action* abound with references and quotations in German, French, Latin, and Greek.⁸)

One of the great good fortunes of my life, that profoundly contributed to my subsequent intellectual devel-

opment, was to be invited by von Mises to attend his graduate seminar at New York University. I received this invitation shortly after my sixteenth birthday, in the last part of my senior year in high school. It came about as the result of a meeting, arranged by The Foundation For Economic Education, between Mises, myself, and Ralph Raico, who was then a fellow student of mine at the Bronx High School of Science (Raico is now Professor of History at the State University of New York, Buffalo). After several hours of conversation, spent mainly answering our questions, Mises invited us both to come to his seminar—provided (in reference to our extreme youth) that we did “not make noise.” We both eagerly accepted his invitation and began attending the very next week.

The format of the seminar was that each semester it was devoted to some topic of special current interest to von Mises, such as inflation or the epistemology of economics. It met on Thursday evenings from 7:25 to 9:05 PM, and, for most of the period in which I attended, at the Gallatin House, which was a fine old town house (once the home of the British consul) located at 6 Washington Square North, in New York’s Greenwich Village. It would open each evening with Mises himself speaking from a few notes for about twenty minutes to half an hour, followed by a general, cross discussion among the various seminar members who wished to participate or who Mises occasionally called upon. Often, a portion of the discussion was devoted to some paper that a seminar participant had prepared for the occasion.

I regularly attended the seminar for about seven and a half years, through the remainder of high school, all through my college years at Columbia University, and then as an enrolled student in NYU’s Graduate School of Business Administration, which was where Mises taught. I stopped attending only when I myself began to teach and had a class of my own to conduct on Thursday evenings.

At the seminar, I had the opportunity of hearing many observations by Mises that were not in his books that I had read. Equally important, I had the opportunity of asking him questions. Uncharacteristically, I did not raise any questions until after I had been in attendance for about a year and a half. Thereafter, I became a full-fledged participant, often being assigned papers to write and deliver.

My most outstanding memory of the seminar is that of Mises himself. I always experienced a heightened level of awareness when he entered the room and took his seat at the seminar table. What I was acutely aware of was that here, just a few feet away from me, was one of the outstanding thinkers in all of human history.

One of the things Mises stressed in his seminar was the importance of knowing foreign languages. One of the

reasons he gave for this was the frequent inadequacy of translation. In this connection, I was very surprised to learn that he was unhappy with the translation of *Socialism*.

I accepted his injunction to learn foreign languages and because there were important writings of his own not yet translated, as well as important writings of Menger and Böhm-Bawerk, his predecessors in the Austrian school, I put the opportunity I had of studying German at Columbia College to very good use. I wholeheartedly plunged into freshman and then sophomore German and memorized every new word I came across, sometimes to the extent of fifty or a hundred words a day. I memorized the declension of every model noun and the conjugation of every model verb, in every tense, mood, and voice, for every person, and every model sentence that I found. The result was that in the Christmas vacation of my sophomore year, I dared to translate a chapter of his *Grundprobleme der Nationalökonomie (Epistemological Problems of Economics)* and then show it to him. Although he had some misgivings, he supported my application for a grant from the William Volker Fund to translate the remainder of the book over the following summer. I obtained the grant and the next summer accomplished the translation at Columbia's Butler Library. I translated four pages a day, Monday through Friday, and three more on Saturday, for ten weeks, until the whole book was done. I worked from nine in the morning until seven in the evening during the week, and from nine until five on Saturdays. When I finished, I typed the manuscript and had copies of it in the hands of the Volker Fund and Mises well before Columbia's fall semester began. I know that both he and the Volker Fund were very favorably impressed, because he urged me to translate Heinrich Rickert's *Kulturwissenschaft und Naturwissenschaft*, which he considered a major answer to logical positivism, over the next summer, and, when I applied for a grant to do it, I got an immediate favorable response. Both translations were published a few years later by D. Van Nostrand, the latter under the title *Science and History*. I have to say that translating Mises, and being well paid to do it at that, was absolutely the most fabulous thing I could think of doing at the time, and to this day, I count it as a major accomplishment of my life.

Some of the credit for my having had the courage to start the translation belongs to the late Murray Rothbard, whom I met when I entered the seminar and became close friends with over the next five years. (Other members of the seminar when I arrived on the scene were Hans Sennholz, now President of the Foundation for Economic Education, and his wife Mary; Israel Kirzner, now a Professor of Economics at New York University; Professor William H. Peterson, then of New York University,

and his wife Mary; and Percy Greaves, who later wrote *Understanding the Dollar Crisis*,⁹ and his wife Bettina Bien Greaves, then and now a staff member of the Foundation for Economic Education. Prominent more or less frequent visitors to the seminar were Henry Hazlitt, then a regular columnist for *Newsweek* as well as the author of numerous books, the best known of which is *Economics in One Lesson*,¹⁰ and Lawrence Fertig, who at the time was a columnist for the *New York World Telegram and Sun*.) Rothbard was then working on his *Man, Economy, and State* on a grant from the Volker Fund and urged me to apply, assuring me that a proposal to translate *Grundprobleme* would be considered both seriously and sympathetically.¹¹

By the time I had been in the seminar for about a year, Rothbard, Raico, and I, were joined by Robert Hessen (now a Senior Fellow at the Hoover Institution in Stanford) and Leonard Liggio (who later became President of the Institute for Humane Studies). About a year after that, Ronald Hamowy (now a Professor of History at the University of Alberta in Edmonton) also joined us. We almost always continued the discussions of the seminar until past midnight, usually at Rothbard's apartment, and frequently met on weekends. We informally called ourselves "The Circle Bastiat," after the leading nineteenth-century French advocate of capitalism, Frederic Bastiat.

At one of our gatherings, in the summer of 1954, over three years before the publication of *Atlas Shrugged*, Rothbard brought up the name Ayn Rand, whom I had not previously heard of. He described her as an extremely interesting person and, when he observed the curiosity of our whole group, asked if we would be interested in meeting her. Everyone in the group was very much interested. He then proceeded to arrange a meeting for the second Saturday night in July, at her apartment in midtown Manhattan.

That meeting, and the next one a week later, had an unforgettable effect on me. In the year or more before I entered Ayn Rand's apartment, I held three explicitly formulated leading intellectual values: liberalism (in the sense in which Mises used the term, and which actually meant capitalism); utilitarianism, which was my philosophy of ethics and which I had learned largely from Mises (though not entirely, inasmuch as I had already come to the conclusion on my own that everything a person does is selfish insofar as it seeks to achieve *his* ends¹²); and "McCarthyism," which I was enthusiastically for, because I believed that the country was heavily infested with communists and socialists, whom I detested, and to whom Senator McCarthy was causing a major amount of upset. By the time I left Ayn Rand's apartment, even after the first meeting, I was seriously shaken in my attachment to utilitarianism.

Both meetings began at about 8:30 in the evening and lasted until about five o'clock the following morning. When I was introduced to her, I had no real idea of her intellectual caliber. I quickly began to learn her estimate of herself, however, when I offered her two tickets to an upcoming dinner in honor of Roy Cohn, Senator McCarthy's chief aide, at which Senator McCarthy would be present. (I was scheduled to make a brief speech at the event, and when I mentioned to one of the event's organizers that I was going to meet Ayn Rand, she asked me to extend the invitation.) Miss Rand declined the invitation on the grounds that to get involved as she would need to get involved, she would have to drop her present project (which was the writing of *Atlas Shrugged*) and do for McCarthy what Zola had done for Dreyfus. I had seen the Paul Muni movie *Zola*, and so had a good idea of Zola's stature. I don't quite remember how I experienced the comparison, but it was probably something comparable to the expression of a silent whistle. (After I came to appreciate the nature of Ayn Rand's accomplishments, a comparison to Zola would seem several orders of magnitude too modest.)

At both meetings, most of the time was taken up with my arguing with Ayn Rand about whether values were subjective or objective, while Rothbard, as he himself later described it, looked on with amusement, watching me raise all the same questions and objections he had raised on some previous occasion, equally to no avail.

I had a sense of amazement at both meetings. I was amazed that I was involved in an argument that in the beginning seemed absolutely open and shut to me, and yet that I could not win. I was amazed that my opponent was expressing views that I found both utterly naïve and at the same time was incapable of answering without being driven to support positions that I did not want to support, and that I was repeatedly being driven into supporting such positions.

Neither of the evenings was very pleasant. At one point—I don't know how we got to the subject, nor whether it occurred at our first or second meeting—I expressed the conviction that a void must exist. Otherwise, I did not see how the existence of motion was possible, since two objects could not occupy the same place at the same time. Ayn Rand's reply to my expression of my conviction was that "it was worse than anything a communist could have said." (In retrospect, recognizing that the starting point of her philosophy is that "existence exists," I realize she took my statement to mean that I upheld the existence of "nonexistence" and was thus maintaining the worst possible contradiction.)

Because of such unpleasantness, I did not desire to see her again until after I read *Atlas Shrugged*. However, I could not forget our meetings and could not help won-

dering if somehow she might be right that values really were objective after all. I was very troubled by the implications of the proposition that all values are ultimately arbitrary and subjective, as Mises claimed. It no longer seemed enough that the great majority of people happened to prefer life to death, and health and wealth to sickness and poverty. For if they happened not to, there would be nothing to say to them that could change their minds, and if there were enough of them, no way to fight them, and, worst of all, no way even morally to condemn any slaughters they might commit, because if all values really were arbitrary and subjective, a concentration-camp sadist's values would be as good and as moral as the values of the world's greatest creators.

The years between my first meetings with Ayn Rand and the publication of *Atlas Shrugged* spanned my sophomore through senior years in college. In that time, I experienced serious intellectual doubt in connection with my ability to defend capitalism. What I had learned from Mises enabled me decisively to answer practically every argument that had been raised against capitalism prior to 1930, which was more than enough to answer my high school teachers. But my college professors presented a different challenge. They were teaching Keynesianism and the doctrine of pure and perfect competition/imperfect competition. Mises, I reluctantly had to conclude, had not dealt adequately with these doctrines.¹³ At any rate, these were two major areas in which I found myself unable to turn to his writings for the kind of decisive help I had come to expect from him.

The doubts I experienced in college were not in response to any kind of solid arguments, but more in response to phantoms of arguments that could not be grasped in any clear, precise way and that in fact usually bore obvious absurdities. This last was certainly true of the Keynesian multiplier doctrine and of the claim on the part of the pure-and-perfect competition doctrine that competition implied the *absence of rivalry*. Despite the absurdities, all of the faculty and practically all of my fellow students at Columbia seemed perfectly at home with the doctrines and absolutely confident of their truth.

If any one concrete can convey the intellectual dishonesty of Columbia's economics department in those days, it was this. Namely, while neglecting to provide a single copy of any of the writings of von Mises, or even so much as mention the existence of any of them in any of the assigned readings or, as far as I was aware, in a classroom, the department saw to it that literally dozens of copies of Oskar Lange's attempted refutation of Mises's doctrine on the impossibility of economic calculation under socialism were available on open reserve in the library—as an optional, supplementary reading in the introductory economics course.¹⁴

Economics was not the only area in college in which I experienced revulsion for Columbia's teachings. I had the same experience in the so-called contemporary civilization courses I had to take, and in history courses. I know I would have had it in philosophy courses, but I wisely dropped the one or two I enrolled in, after the first week. There were, to be sure, things I valued at college, having greatly gained from them: such as having to read the great classics of Western literature, which I would probably not have done on my own; the freshman English-composition course, which gave me the ability to write a solid essay; the German courses; and the mathematics courses. However, with the exception of three of the mathematics courses, almost all of these were in the first two years. By the time of my senior year, I had profoundly soured on Columbia University. I remember walking the campus and noting the names of the various buildings: "School of Mines," "School of Engineering," "Philosophy Hall," and so on. I remember thinking that the first two served honorable purposes, while the third served no purpose but the emission of intellectual poison.

I do not know if my college education could have damaged my intellectual development permanently. It did not have the chance. For just a few months after graduation, *Atlas Shrugged* appeared.

I obtained a very early copy and began to read it almost immediately. Once I started it, I could not put it down, except for such necessary things as eating and sleeping. I was simply pulled along by what I have thought of ever since as the most exciting plot-novel ever written. Every two hundred pages or so, the story reached a new level of intensity, making it even more demanding of resolution than it was before. I stopped only when I finally finished the book, four days after I had started it. When I finished, the only thing I could find to say in criticism, tongue in cheek, was that the book was too short and the villains were not black enough.

The first thing I got out of *Atlas Shrugged* and the philosophical system it presented was a powerful reinforcement of my conviction that my basic ideas were right and a renewal of my confidence that I would be able to expose my professors' errors.

Very soon thereafter, the whole Circle Bastiat, myself included, met again with Ayn Rand. We were all tremendously enthusiastic over *Atlas*. Rothbard wrote Ayn Rand a letter, in which, I believe, he compared her to the sun, which one cannot approach too closely. I truly thought that *Atlas Shrugged* would convert the country—in about six weeks; I could not understand how anyone could read it without being either convinced by what it had to say or else hospitalized by a mental breakdown.

The following winter, Rothbard, Raico, and I, and, I think, Bob Hessen, all enrolled in the very first lecture

course ever delivered on Objectivism. This was before Objectivism even had the name "Objectivism" and was still described simply as "the philosophy of Ayn Rand." Nevertheless, by the summer of that same year, 1958, tensions had begun to develop between Rothbard and Ayn Rand, which led to a shattering of relationships, including my friendship with him.¹⁵

Shortly after that break, I took Rothbard's place in making a presentation in Ayn Rand's living room of the case for "competing governments," i.e., the purchase and sale even of such government services as police, courts, and military in a free market. As the result of Ayn Rand's criticisms, I came to the conclusion that the case was untenable, if for no other reason than that it abandoned the distinction between private action and government action and implicitly urged unregulated, uncontrolled government action, i.e., the uncontrolled, unregulated use of physical force. This was the logical implication of treating government as a free business enterprise. I had to conclude that government in the form of a highly regulated, tightly controlled legal monopoly on the use of force, was necessary after all, in order to provide an essential foundation for unregulated, uncontrolled private markets in all goods and services, which would then function totally free of the threat of physical force. This indeed, represented nothing more than a return to my starting point. It was what the government established by the United States' Constitution had represented, and which I had so much admired.

At that time, and in later years, I came to be influenced by Ayn Rand's ideas in numerous ways, thanks in part to the fact that over the years between 1957 and her death in 1982, I had the opportunity of frequently meeting with her and speaking with her extensively about her writings. The influence of her philosophy extolling individual rights and the value of human life and reason appears repeatedly in this book and sets its intellectual tone. To be specific, I have found her treatment of the concepts of individual rights and freedom to be far superior to that of anyone else, and I have taken it over and have applied it extensively both in Chapter 1 and as the foundation of my treatment of monopoly as inherently government created in Chapter 10. In Chapter 1, very much in the spirit of Ayn Rand, I have shown how the whole of capitalist development, including the development of the panoply of capitalism's institutions from private ownership of land to the division of labor and continuous economic progress, can be understood as "a self-expanded power of human reason to serve human life."¹⁶ In Chapter 2, I have made her views on the role of reason in human life, on the objectivity of values, and on the integration of mind and body essential elements of my approach to the foundations of economics, that is, to

man's objective need both for the constantly growing supply of wealth that capitalism produces and for the science of economics itself. Her influence pervades my critique of environmentalism in Chapter 3. It is present in my discussion of competition in Chapter 9, where I have adopted her principle of the "pyramid of ability" and integrated it with the law of comparative advantage. It appears in my critique of the doctrine of pure and perfect competition in Chapter 10, much of which was originally published in *The Objectivist* under her editorship. It is also to be found in the epistemological aspects of Chapters 11, 15, and 18, that is, in my approach to definitions, axiomatic concepts, and the epistemological errors of Keynes and his followers. Her influence is probably to be found in some measure in every chapter, at the very least insofar as it has contributed to an improved ability on my part to know what is a forceful argument and what is not. Needless to say, it is very much present in my treatment of the philosophical influences that led to the development of capitalist civilization and the current philosophical influences that are threatening to destroy it, and, of course, everywhere insofar as I deal with such essential matters as egoism versus altruism, individualism versus collectivism, and reason versus mysticism.

Looking back over the past and all that has led to the writing of this book, I cannot help but take the greatest possible pride and satisfaction in the fact that along the way, in having been the student of *both* Ludwig von Mises and Ayn Rand, I was able to acquire what by my own standards at least is the highest possible "intellectual pedigree" that it is possible for any thinker to have acquired in my lifetime, or, indeed, in any other lifetime.

The year and a half or more following my abandonment of the doctrine of competing governments turned out to be the most intellectually productive of my life, and to provide most of what is original in this book. The distinctive intellectual background of that period included a long-standing disagreement I had had with Rothbard concerning whether or not the rate of profit ("originary interest" in the terminology of Mises) had to fall in connection with capital accumulation. Rothbard maintained that it did, as did the overwhelming majority of economists since the time of Adam Smith. To me, such a position seemed comparable to implying the gradual extinction of the sun as the necessary accompaniment of capital accumulation. For it was only the prospect of profit that provided motivational energy to the entire economic system. And while Mises's own position on this subject was unclear, he held another doctrine of similar import. This was his doctrine of purchasing-power price premiums in the rate of interest, according to which the prospect of prices rising at any given rate added an equivalent percentage to the rate of interest,

while the prospect of prices falling at any given rate resulted in an equivalent deduction from the rate of interest. Thus formulated, an implication of this doctrine, I concluded, was that rapid increases in production that caused a rapid fall in prices would result in a negative rate of interest and thus in a lack of all incentive to lend or invest, and thus in a depression. This conclusion too was unacceptable to me. It implied the overproduction doctrine, which Mises himself, of course, totally opposed.¹⁷

I compiled a written list of such points, which also included numerous questions I had come to formulate in connection with my classes at Columbia and then at NYU, where I was now enrolled in the doctoral program.

By this time, in just a year and two summers, taking ten two-credit courses in the fall and ten in the spring, I had already completed all of the course work for a Ph.D., but I still had the written and oral exams and the dissertation in front of me. My original plan had been to go straight through for the Ph.D., in the shortest possible time. Now I found the prospect of the obstacles that still remained to be somewhat more daunting, and so I decided that it would be worthwhile to take a few months out and obtain an MBA degree. For this, all I needed to do was write an MBA thesis.

I decided to choose a topic that would require that I read only "good people"—i.e., sound authors. I had come to the conclusion that because the efforts of proto-Keynesians, such as Malthus and Sismondi, had been decisively defeated by the classical economists in the early nineteenth century, and because nothing like the pure-and-perfect-competition doctrine had ever even arisen in the nineteenth century, when classical economics was in vogue, there must have been something in classical economics that served to refute or thoroughly preclude such doctrines in the first place, and thus that I should turn to it once again as a source of knowledge. The thesis topic I chose was *The Classical Economists and the Austrians on Value and Costs*. This topic required that I read extensively in Menger, Böhm-Bawerk, and Wieser for the Austrian views, and not only in Smith and Ricardo, but also in James Mill, Say, McCulloch, Senior, and J.S. Mill, for the views of classical economics.

This project turned out to be a very good idea, indeed. I learned much more about the doctrine of diminishing marginal utility, including how it subsumes cases in which prices are actually determined in the first instance by cost of production.¹⁸ In reading seven different classical authors, each one covering essentially the same ground, and doing so at the age of twenty-one and twenty-two, instead of thirteen, I was able to come to a genuine understanding of their work. This included seeing how their views on the labor theory of value and the

“iron law of wages” greatly differed from those of Marx, whose views on these subjects are usually assumed to be the same as theirs, and that Ricardo’s doctrine that “profits rise as wages fall, and fall as wages rise” did not, despite all appearances, actually imply a conflict of interests between wage earners and capitalists.¹⁹ I came to see, in fact, that very little substantive difference actually existed between the views of Böhm-Bawerk and those of John Stuart Mill concerning the determination of the prices of reproducible products.²⁰ Very importantly, I began to see how the whole contemporary approach of “imperfect competition” versus “pure and perfect competition” was a result of the abandonment of the classical economists’ recognition of the role of cost of production in the determination of the prices of reproducible goods, a recognition that Böhm-Bawerk and Wieser had retained but all others had apparently lost.²¹

What I gained from the extensive reading I had done in connection with my thesis went far beyond the subject of value and costs. In the months immediately following, I knew that I had learned a great deal that had not gone into the thesis—knowledge that I could then not yet even explicitly formulate. I felt good about my state of mind and I am pretty sure that I described my mental condition to myself as one of being “intellectually pregnant.”

Back in the spring of 1958, I had succeeded in formulating to my own satisfaction a set of conditions in which capital accumulation could take place indefinitely with no accompanying fall in the rate of profit. I had tried to explain it to Rothbard, but without success. That demonstration was one element in the back of my mind, before I even got to the reading for my thesis. My exposure to principles of actual business accounting, as the result of having taken a number of courses on investments and corporation finance in the NYU program, provided another critical element besides what I had learned from my reading.

In July of 1959, it all came together. The precipitating event was my reading an extensive quotation from John Stuart Mill presenting the proposition that “demand for commodities is not demand for labour.” This was a passage I had not read before. It appeared in Henry Hazlitt’s newly published *The Failure of the “New Economics.”*²²

Very soon thereafter, I had a period of five successive days in which I was able to make one connection after another and to answer one question after another from my list. In essence, I had put together, and was able to hold in my mind all at the same time, an early version of what now appears in this book as Figures 16–2 and 17–1 and derive a succession of major implications from it.²³

I saw how Mill’s proposition was essential to explaining an *excess* of the demand for the products of business

over the demand for factors of production by business. It was only because the demand for “commodities”—viz., consumers’ goods—was not a demand for labor that the demand for consumers’ goods could *exceed* the demand for labor, and thus that the demand for the products of business in general could exceed the demand by business for factors of production in general. This excess of demand for products over demand for factors of production was an essential cause of an excess of sales revenues over costs, and, therefore, of an aggregate profit in the economic system. I could see at the same time how with a given aggregate amount and average rate of profit, based on a given excess of the demand for the products of business over the demand for factors of production by business, both capital accumulation and falling prices caused by increased production could take place, with, of course, no effect whatever on the average rate of profit. I could also see other important relationships. In those five days, I was able to grasp essential portions of what are now Chapters 11 and 13–18 of this book. Virtually everything else that is in these chapters, and much that is in other chapters, is an elaboration or further implication of the discoveries I made in those five days, though in many cases, the elaboration or further implication did not occur to me until much later. Indeed, the process of tracing out the implications continues down to the present.

As I made the new connections I wrote them down, sometimes jumping out of bed to do so, lest I forget any of them. After the first five days, I had accumulated about 15 pages of notes, the most important part of which was an elaborate numerical example of the most essential points in a form consistent with the principles of business accounting. In August, I wrote a hundred-page-plus typed paper called “The Consumption Theory of Interest,” which I showed to Henry Hazlitt, who, as mentioned, sometimes attended von Mises’s seminar. He was generally impressed with it, and, starting with the third printing of *The Failure of the “New Economics,”* credited me with an important application I had made in the paper identifying a simultaneous breakdown of the Keynesian doctrines on consumption, employment, liquidity preference, and the rate of interest, though he did not refer to my manuscript specifically.²⁴

Not long after I made my discoveries, I decided that they should be the main subject of my doctoral dissertation, which I began to do research for soon after passing my oral examination in the spring of 1960. For the sake of thoroughness, I wanted to include not only my own views, but also a critical analysis of all significant alternative views. I set out to follow the example of Böhm-Bawerk, who had done just that. Thus, in preparation for writing my dissertation, I read virtually all of Böhm-Bawerk that I had not previously read, as well as major

selections from other authors whose views concerning the rate of profit/interest were prominent, such as Irving Fisher, Knut Wicksell, and Frank Fetter, as well as Smith, Ricardo, other classical economists, and Marx and Keynes.

I began writing the dissertation in May of 1961 and handed in a 625-page typed manuscript in the fall of 1962. The title was *The Theory of Originary Interest*. (At this time, I still followed Mises in describing what businessmen and accountants normally describe as profit, and which I too now refer to as profit, as “originary interest.”)

In January of 1963, I learned that one of the members of my reading committee had rejected the dissertation. In order to gain his approval, it was necessary for me to eliminate well over half of the manuscript I had submitted, and write approximately thirty new pages at the beginning and thirty more new pages at the end. (On my own initiative, I replaced “originary interest” with “profit” throughout.) The last time I spoke with this committee member, he said he liked the new version much better than the original one, except for the first thirty pages; he also said he had not yet read the last thirty pages. (Sometime later, I was told that this individual had left the university to write editorials for *The Washington Post*.) My dissertation, as finally approved, carries the title *The Theory of Aggregate Profit and the Average Rate of Profit*.²⁵

This situation constituted the one time in my life when I was seriously disappointed in von Mises. He told me that he found it amusing that I should receive such trouble from this particular committee member, whom he regarded as a Marxist, when what I was providing was a modernized, more scientific version of the very ideas that were the foundation of the man’s own beliefs. Mises believed that because of my resurrection of the classical economists, I was indirectly resurrecting Marx. (Happily, he changed his mind on this subject two years later, after hearing my lecture “A Ricardian’s Critique of the Exploitation Theory.”²⁶ But the same essential material had been available to him in my original dissertation.)

As much of the preceding makes clear, this book is very much the product of ideas I first developed over thirty-five years ago and have been further developing and elaborating ever since. Over this period, I have published various portions of my ideas in articles. In

Laguna Hills, California
June 1996 and March 1997

Postscript, June 1999. The author’s website www.capitalism.net provides extensive lists of study-review questions and supplementary readings for this book, on a

cases in which I have been unable to improve upon formulations I presented in those articles, I have retained the formulations. Appropriate acknowledgment is made to the publications in question in notes to the portions of the text where the formulations appear.

Here I wish to express my special thanks to Libertarian Press for its permission to include the very lengthy quotation from Böhm-Bawerk’s *Capital and Interest* that appears on pp. 414–416.

I have not sought permission from any publisher to quote passages in cases in which direct quotation is necessary to prove to the reader that the author in question really does hold the views I ascribe to him. Here I rely on the doctrine of fair use, which I believe provides protection against the intellectual hit and run that would be entailed in allowing authors to propound absurd and vicious ideas and then to hide behind copyright protection so that a critic could not prove what they had actually said and thus be placed at risk of being accused of having presented their views unfairly. This applies above all to my numerous quotations from various editions of the textbook *Economics* by Paul Samuelson. It also applies to my quotations from less well-known textbooks, from *The General Theory* by Lord Keynes, *The New Industrial State* by John Kenneth Galbraith, and from sundry environmentalists.

I would like to acknowledge here the very generous financial support provided by Mr. Michael Aronstein of New York, in making possible the first printing of this book. Mr. Aronstein is one of the very few businessmen and capitalists who understands both the truth of pro-capitalist economic theory and the importance of disseminating that truth to the educated public.

Above all, however, I want to acknowledge the very great contribution of my wife, Dr. Edith Packer, with whom I have now shared most of my adult life. I doubt very much that I could have undertaken, let alone carried to completion, a project of this size without her. She has provided both the necessary emotional framework and an extremely helpful intellectual framework. It was she who served as the first reader and editor of the manuscript of this book. An important part of the organization and much of the readability of my book are due to her suggestions.

GEORGE REISMAN

chapter-by-chapter basis. It also features the book as the centerpiece of a program of self-education in the economic theory and political philosophy of a capitalist society.

Notes

1. These were the tape-recorded lecture series that are known as *An Introduction to Procapitalist 'Macroeconomics,' A Theory of Productive Activity, Profit, and Saving*, and *Capital, the Productive Process, and the Rate of Profit*. These titles and the one described in the next sentence of the text are available on CDs, in MP3 format, from The Jefferson School at PO Box 2934, Laguna Hills, Calif., 92654.
2. Thus, my 1990 TJS Fall seminar lecture "The Nature and Value of Economics" was a portion of Chapter 1. My 1991 TJS summer conference series *Wealth, Natural Resources, and the Environment* and *The Political Concept of Monopoly* was drawn from Chapters 2, 3 and 10.
3. Concerning the errors of this view, see below, pp. 473–500.
4. William Stanley Jevons, *The State in Relation to Labour* (London: Macmillan and Co., 1894); *The Theory of Political Economy*, 4th ed. (London: Macmillan and Co., 1924).
5. I happened to buy *The State in Relation to Labour* as the result of not being able to afford Jeremy Bentham's *In Defence of Usury*, a work whose title greatly appealed to me, and thus having to choose the substantially less expensive title by Jevons.
6. The essay has been reprinted in Ludwig von Mises, *Planning For Freedom*, 4th ed. enl. (South Holland, Ill.: Libertarian Press, 1980).
7. Ludwig von Mises, *Socialism* (New Haven: Yale University Press, 1951); reprint ed. (Indianapolis: Liberty Classics, 1981).
8. Happily, these have been translated in the currently available Liberty Classics reprint edition of *Socialism* cited above. As a major aid to reading *Human Action*, see *Mises Made Easier A Glossary for Human Action* prepared by Percy L. Greaves, Jr. (Dobbs Ferry, N. Y.: Free Market Books, 1974).
9. Percy Greaves, *Understanding the Dollar Crisis*, (Belmont, Mass.: Western Islands, 1973).
10. Henry Hazlitt, *Economics in One Lesson*, new ed. (New Rochelle, N. Y.: Arlington House Publishers, 1979).
11. Murray N. Rothbard, *Man, Economy, and State*, 2 vols. (Princeton, N. J.: D. Van Nostrand Company, Inc., 1962).
12. This is a conclusion that I now consider to be mistaken, because it attaches no objective meaning to the concept of self.
13. This conclusion may appear somewhat ironic in view of the fact that what is today accepted as a new and convincing major critique of Keynesianism, namely, the "rational expectations doctrine," is nothing more than arguments made by Mises and Hazlitt in the 1950s, for which they have received no credit. See, for example, Paul Samuelson and William Nordhaus, *Economics*, 15th ed. (New York: McGraw Hill Book Company, 1995), Figure 31–5 on p. 613 and the surrounding discussion. Then see Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 792–793. See also below, p. 6 and p. 11, n. 15.
14. See Oscar Lange, *On the Economic Theory of Socialism*, Benjamin E. Lippencott, ed. (Minneapolis: University of Minnesota Press, 1938). See also below, my critique of Lange and his doctrine of the artificial market, on pp. 279–282.
15. When I knew Rothbard, he was a staunch pro-McCarthy, anticommunist. Later on, incredible as it may seem, he became *an admirer of the Soviet Union!* For evidence of this, see below, p. 11, n. 13.
16. See below, pp. 19, 27–28.
17. For demonstrations of why capital accumulation does not entail a falling rate of profit and of why falling prices caused by increased production do not reduce the rate of profit or interest, see below, pp. 569–580, 810–818, and 825–826.
18. On this point, see below the lengthy quotation from Böhm-Bawerk on pp. 414–416.
19. Concerning these points, see below, pp. 475–498.
20. See below, p. 218, n. 31.
21. On this subject, see below, pp. 408–417.
22. Henry Hazlitt, *The Failure of the "New Economics"* (New York: D. Van Nostrand, 1959), p. 363.
23. Figures 16–2 and 17–1 are shown facing each other on pp. 810–811.
24. See Henry Hazlitt, *The Failure of the "New Economics,"* 3d printing, and later, p. 196, n. 6.
25. George Reisman, *The Theory of Aggregate Profit and the Average Rate of Profit*, Ph.D. diss., New York University Graduate School of Business Administration (1963; reprinted by University Microfilms, Inc., Ann Arbor, Mich.).
26. The substance of this lecture was published many years later as my essay "Classical Economics Versus the Exploitation Theory" in Kurt Leube and Albert Zlabinger, eds., *The Political Economy of Freedom Essays in Honor of F. A. Hayek* (Munich and Vienna: Philosophia Verlag, 1985). The same analysis, greatly elaborated, appears below, on pp. 473–498.

INTRODUCTION

The subject of this book is the principles of economics. Its theme is that the application of these principles to the service of human life and well-being requires the existence of a capitalist society.

The purpose of this introduction is to enable the reader to classify the present book in relation to the wider body of procapitalist economic thought and of economic thought as such.

1. Procapitalist Economic Thought, Past and Present

Procapitalist economic thought and economic thought as such are essentially synonymous. The substance of both is to be found in the same two main sources, namely, the writings of the British (and French) classical economists and the Austrian neoclassical economists. All other schools of economic thought are essentially either just prescientific gropings or nothing more than misguided criticisms of the positive truths established by the classical and Austrian schools.

Among the classical economists are, above all, Adam Smith (1723–90), David Ricardo (1772–1823), James Mill (1773–1836), and John Stuart Mill (1806–73), and the Frenchmen Jean-Baptiste Say (1767–1832) and Frederic Bastiat (1801–50). The nineteenth-century Englishmen Nassau W. Senior (1790–1864), John R. McCulloch (1789–1864), and John Cairnes (1824–75) also deserve mention as important members of this group. Important close allies of the classical school are the Manchester school, led by Richard Cobden (1804–65) and John Bright (1811–89), who were the parliamentary leaders of the British

free-trade movement in the mid-nineteenth century, and the currency school, which included the English economists Lord Overstone (1796–1883) and Robert Torrens (1780–1864), and the American monetary theorists William Gouge (1796–1863) and Charles Holt Carroll (1799–1890). The classical school incorporated important economic truths previously identified by Richard Cantillon (1680–1734), David Hume (1711–76), and, above all, the French Physiocrats. The Physiocrats flourished around the middle of the eighteenth century. The leading members of the school are François Quesnay (1694–1774), Pierre Du Pont de Nemours (1739–1817), Robert Jacques Turgot (1727–81), and Mercier de la Rivière (1720–93). The great merit of the Physiocrats was to have identified the existence of natural economic laws (*physiocracy* means the rule of nature) and, on the basis of their understanding of those laws, to have reached the conclusion that the government should follow a policy of *laissez faire*, a term which they originated.¹

The most important members of the Austrian school are Carl Menger (1840–1921), Eugen von Böhm-Bawerk (1851–1914), and Ludwig von Mises (1881–1973). Other important members are Friedrich von Wieser (1851–1926); F. A. Hayek (1899–1992), who was the most prominent of von Mises's students and who won the Nobel prize for economics in 1974; Henry Hazlitt (1894–1993); Murray Rothbard (1926–95), who was one of von Mises's later students; and, among the later students of von Mises who are still alive, Hans Sennholz and Israel Kirzner.²

Closely allied with the Austrian school on many points

are the major neoclassical English economists William Stanley Jevons (1835–82) and Philip Wicksteed (1860–1927), the major Swedish economist Knut Wicksell (1851–1926), and the major mid-nineteenth-century German economist Hermann Heinrich Gossen (1810–58), who had anticipated some of its leading doctrines in a book published in 1854. Other major economists who are more or less significantly allied with the Austrian school are the Americans John Bates Clark (1847–1938), Frank Fetter (1863–1949), Irving Fisher (1867–1947), and Frank Knight (1885–1972), who were prominent earlier in this century. The contemporary Chicago school, led by Milton Friedman, and its offshoot the Public Choice school, headed by James Buchanan, also fall into the category of allies of the Austrian school. (Friedman won the Nobel prize in economics in 1976; Buchanan, in 1986.) Other, less well-known but important contemporary or recent economists who are more or less significantly allied with the Austrian school and sympathetic to capitalism are Armen Alchian, William Allen, Dominick Armentano, Paul Heyne, Wayne Leeman, John S. McGee, Mark Skousen, Thomas Sowell, Walter Williams, Leland Yeager, and the late W. H. Hutt (1899–1988) and Ludwig Lachmann (1906–1990). And there are many more, both here in the United States and abroad. Both the Austrian school and its allies have been heavily influenced in turn by the writings of the classical economists.

It should not be surprising that such a large number of those who are recognized as important economists are, at the same time, leading advocates of capitalism. To the extent that an economist really understands the principles governing economic life, and desires that human beings live and prosper, he can hardly fail to be an advocate of capitalism.

The classical and Austrian schools have had important allies in the field of philosophy. Ayn Rand (1905–82), in particular, must be cited as providing a philosophical foundation for the case for capitalism, and as being responsible probably more than anyone else for the current spread of procapitalist ideas. The great English philosopher John Locke, who was a leading intellectual influence on the Founding Fathers of the United States, also deserves an especially prominent mention. And the English philosophers Jeremy Bentham and Herbert Spencer must be cited as well.

The classical and the Austrian schools and their allies have developed virtually all of the great positive truths of economic science. Their ideas, especially those of von Mises, Ricardo, Smith, and Böhm-Bawerk—in that order—together with important elements of the philosophy of Ayn Rand—are the intellectual foundation and inspiration of this book, which seeks to carry the work of these extraordinary individuals a step further by integrating

leading elements of it into a logically consistent whole and by incorporating the present author's own contributions.

Because the whole of this book is itself an exposition of the ideas of the classical and Austrian economists, it is not necessary (nor would it be possible) to explain at this point precisely what it is that these economists maintain, beyond a few generalities. They recognize the gains derived from the division of labor. They explain the nature, origin, and importance of money; the laws governing the determination of prices, wages, profits, and interest; and the vital role of saving and capital accumulation in raising the standard of living. They understand the benevolent nature of self-interest and the profit motive operating under economic freedom, and show how government intervention is the cause of inflation, depressions, economic stagnation, poverty, international economic conflict, and wars. In sum, they support capitalism and oppose government interference and socialism. To a great extent, the views of these authors will become clear in the pages that follow. But, because this is not a book on the history of economic thought, no systematic effort is made to explain precisely which individuals held which specific positions. The reader who is interested in acquiring that knowledge is advised to consult the bibliography, which appears at the end of this book, and to undertake the immeasurably valuable task of reading through the works listed in it.

A subject which must be dealt with here, however, is a brief account of the *differences* between the classical and Austrian schools. The leading difference concerns the theory of value and price. The classical economists, with exceptions, assigned an exaggerated role to cost of production as an explanation of prices, and, as a consequence, to the quantity of labor required to produce goods. They even went so far as frequently to maintain that wages are determined by “the cost of production of labor.” Wages, they often held, tend to equal the price of the goods necessary to enable a worker to live and to raise replacements for himself and his wife.

Such an exaggerated role assigned to cost of production and quantity of labor made it possible later in the nineteenth century for Karl Marx to present himself as the logical heir of the classical economists, devoted merely to developing the implications of their doctrines. Marx was believed, and the consequence was that when the Austrian and other neoclassical economists appeared on the scene around 1870 and propounded the theory of marginal utility as the explanation of value and price, the doctrines of classical economics were abandoned to an extent much greater than necessary, to the great loss of later economic science. Only those doctrines were retained that could be supported either on the basis of the

theory of marginal utility or otherwise independently of the basic classical framework. In terms of what was lost intellectually, it was a case of the classical economics baby being thrown out with the Marxist bath water. Ironically, those who threw out the baby were precisely the people who needed it most and to whom it really belonged—namely, the later advocates of capitalism.

Significantly, the abandonment of classical economics was also brought about by the growing influence of socialism. And to this extent, it was clearly a case of the abandonment being caused by classical economics' *anti-socialist* implications. What I refer to was the altogether unjustified recantation in 1869 of a central pillar of classical economics by its then leading spokesman, John Stuart Mill. In response to utterly flimsy criticisms, easily capable of being answered, and apparently based on nothing more than his own growing attachment to socialist ideas, Mill abandoned the so-called wages-fund doctrine, according to which wages are paid out of savings and capital. In so doing, he cut the ground from under the entire classical perspective on the role of saving and capital in the productive process, including his own previous brilliant contributions to that perspective, and set the stage for the intellectual success of Keynesianism in the 1930s.³

The theory of marginal utility resolved the paradox of value which had been propounded by Adam Smith and which had prevented the classical economists from grounding exchange value in utility. "The things which have the greatest value in use," Smith observed, "have frequently little or no value in exchange; and on the contrary, those which have the greatest value in exchange have frequently little or no value in use. Nothing is more useful than water: but it will purchase scarce any thing; scarce any thing can be had in exchange for it. A diamond, on the contrary, has scarce any value in use; but a very great quantity of other goods may frequently be had in exchange for it."⁴

The only explanation, the classical economists concluded, is that while things must have utility in order to possess exchange value, the actual determinant of exchange value is cost of production. In contrast, the theory of marginal utility made it possible to ground exchange value in utility after all—by showing that the exchange value of goods such as water and diamonds is determined by their respective *marginal* utilities. The marginal utility of a good is the utility of the particular quantity of it under consideration, taking into account the quantity of the good one already possesses or has access to. Thus, if all the water one has available in a day is a single quart, so that one's very life depends on that water, the value of water will be greater than that of diamonds. A traveler carrying a bag of diamonds, who is lost in the middle of

the desert, will be willing to exchange his diamonds for a quart of water to save his life. But if, as is usually the case, a person already has access to a thousand or ten thousand gallons of water a day, and it is a question of an additional quart more or less—that is, of a marginal quart—then both the utility and the exchange value of a quart of water will be virtually nothing. Diamonds can be more valuable than water, consistent with utility, whenever, in effect, it is a question of the utility of the first diamond versus that of the ten-thousandth quart of water.

A fundamental accomplishment of this book, which makes possible almost all of its other accomplishments, is *the integration and harmonization of the ideas of the classical and Austrian economists*. This has made it possible for me to modernize and reintroduce into economic analysis several of the major doctrines of the classical economists which were abandoned unnecessarily, and thereby to add greatly increased strength to the central ideas of von Mises and the Austrian school. A leading application of the classical doctrines, of which I am especially proud, and which I hasten to name, is a radically improved critique of the Marxian exploitation theory. In my judgment, classical economics makes possible a far more fundamental and thoroughgoing critique of the exploitation theory than that provided by Böhm-Bawerk and the Austrian school, despite the prevailing mistaken belief that it implies the Marxian exploitation theory.⁵ It also provides the basis for greatly strengthening the refutation of the ideas of Keynes and of the doctrine that big business implies "monopoly power."

Among the classical doctrines I have reintroduced is the recognition of saving and productive expenditure, rather than consumption expenditure, as the source of most spending in the economic system. Closely related to this, I have brought back the wages-fund doctrine and have made clear the meaning of John Stuart Mill's vital corollary proposition that "demand for commodities does not constitute demand for labor." I have reinstated Adam Smith's recognition that in a division-of-labor society the concept of productive activity must incorporate the earning of money and that because of its failure to earn money, government is a consumer. I have reintroduced Adam Smith's and James Mill's conception of the role of saving in relation to the disposition of "the gross annual produce" between consumers' goods and capital goods, and James Mill's conception of what has unjustly come to be known as *Say's Law*.⁶ Along with this, I have reintroduced Ricardo's insights that capital can be accumulated not only by saving but also by anything else that serves to increase wealth, and that technological progress operates not to raise the general rate of profit but to reduce prices (and, implicitly, to increase the supply of

capital goods). I have also reintroduced Ricardo's profound recognition of the distinction between "value and riches" and of the need for the concept of an invariable money as a methodological device in developing economic theories. I have even gone so far as to interpret Ricardo's proposition that "profits rise as wages fall and fall as wages rise"—a proposition that on its face appears to imply class warfare—in the light of the assumption of an invariable money. I have found that when interpreted in this light, the proposition both serves in the overthrow of the exploitation theory and points the way to a sound theory of profits. I have also found it extremely useful to revive the classical economists' conception of demand and supply as a ratio of expenditure to quantity sold, and to employ it no less than the contemporary conception of demand and supply as schedules of quantities demanded and supplied at varying prices.

I have used the classical economists' insights to develop a substantially new theory of the rate of profit and interest; a new theory of saving and capital accumulation; a radically new theory of aggregate economic accounting, which features the role of saving and productive expenditure; new definitions of such fundamental economic concepts as capital goods and consumers' goods; and a theory of wages that is also new in major respects.

The main thing I have discarded in classical economics is any notion that wages are determined by "the cost of production of labor." On the contrary, I show that the essential economic function of businessmen and capitalists is to go on raising the productivity of labor and thus to raise the standard of living of the average wage earner by bringing about a reduction in prices relative to wages—that is, to bring about a progressive rise in so-called real wages. I have not discarded the role of cost of production as a determinant of the prices of *products*, however. Ironically, here I have been inspired by Böhm-Bawerk and Wieser, who clearly recognized cost of production as being usually the direct, immediate determinant of prices in the case of manufactured or processed goods and who explained how the determination of price by cost was fully consistent with the principle of marginal utility—indeed, was a manifestation of the principle of marginal utility.⁷ When all is said and done, I believe I have succeeded in grounding the work of the Austrian school in foundations supplied by the classical school—foundations, of course, which have been cleared of major errors. Among the major themes of my book that are derived from classical economics, in addition to those already described, are: production, not consumption, is the essential economic problem; production throughout is supported by capital; and the central economic figure is the businessman, not the wage earner and not the consumer. These views are in opposition both to Marx-

ism and, in part, to those of the Austrian school, which, I believe, has overemphasized the role of the consumer.

The consumers, it is true, have the power, by virtue of the pattern in which they spend their incomes, to decide which investments of the businessmen turn out to be profitable and which unprofitable, and thus, in the last analysis, to govern the pattern of investment, as businessmen compete for their favor. The consumers' valuations and the spending patterns that result from them also determine the relative prices of the factors of production—for example, the wages of skilled labor relative to the wages of unskilled labor, the prices of real estate in one location relative to those in other locations, and the relative prices of capital goods insofar as their production cannot immediately be varied in response to changes in demand. And, of course, they also directly determine the relative prices of consumers' goods, insofar as the supply of consumers' goods cannot immediately be varied in response to changes in demand.

Nevertheless, the funds of the consumers come from business and the whole of their consumption is supported by production and the productive process. The individual business is dependent on the consumers because it is directly or indirectly in competition with all the other business firms in the economic system, and it is up to the consumers to decide which business firms to buy from. But from the point of view of the economic system as a whole, it is the consumers who are dependent on business. They have the power to consume only by virtue of making a contribution to production. And whatever funds they so receive, they will assuredly spend, sooner or later, in buying from some business or other. For money qua money is absolutely useless except as a means of obtaining goods or services.

Furthermore, a major finding of this book is that while the consumers determine the *relative* prices of the factors of production, such as the wages of skilled labor relative to those of unskilled labor, the consumers do not determine the *absolute* height of the prices of the factors of production. The absolute height of the prices of the factors of production is determined by the extent of *saving*, and is the greater, the greater is the extent of saving, and the smaller, the less is the extent of saving. Consumption relative to saving, it is shown, is the major determinant of the extent to which the prices of consumers' goods (and of capital goods too) *exceed* the prices of the factors of production used to produce them—that is, it is the major determinant of the rate of profit and interest.⁸

These views do not represent any real or fundamental break with the views of the Austrian school but, on the contrary, in vital respects are supported by them. For example, it will be shown that a rise in saving and fall in

consumption does not operate to raise the prices of factors of production above the prices of consumers' goods and thereby plunge the economic system into losses and a depression. What happens is merely what the Austrian school would call "a lengthening of the structure of production." Greater saving relative to consumption means that there is not only more spending for capital goods and labor to produce consumers' goods, but also, and even primarily, more spending for capital goods and labor to produce *capital goods*. The productive expenditure of the greater savings is a deduction not merely from a diminished consumption expenditure, but from an enlarged demand for capital goods, which takes the place of the diminished demand for consumers' goods. The demand for capital goods is as much a source of business sales revenues as the demand for consumers' goods. In the last analysis, what happens is that labor comes to be employed in the performance of work that is temporally more remote from its ultimate results in the form of consumers' goods.⁹

I believe that by the time the reader finishes this book, he will share my conviction that in fundamental essentials, the classical and Austrian schools are not in conflict, but represent major, complementary elements of the same great body of truth. I even believe that he will be able to read Böhm-Bawerk and John Stuart Mill on the subject of prices and costs and no longer see any fundamental or essential differences between them.¹⁰

One economist above all others must be singled out as *the* leading intellectual defender of capitalism, namely, Ludwig von Mises. When von Mises appeared on the scene, Marxism and the other socialist sects enjoyed a virtual intellectual monopoly. As explained, major flaws and inconsistencies in the writings of Smith and Ricardo and their followers enabled the socialists to claim classical economics as their actual ally. The writings of Jevons and the early Austrian economists—namely, Menger and Böhm-Bawerk—were insufficiently comprehensive to provide an effective counter to the socialists. Bastiat had tried to provide one, but died too soon, and probably lacked the necessary theoretical depth in any case.

Thus, when von Mises appeared, there was virtually *no systematic intellectual opposition to socialism or defense of capitalism*. Quite literally, the intellectual ramparts of material civilization were undefended. What von Mises undertook, and which summarizes the essence of his greatness, was *to build a systematic intellectual defense of capitalism and thus of material civilization*.

Point for point, von Mises developed answers to virtually all of the accusations made against capitalism—from its alleged exploitation of labor and responsibility for unemployment and depressions to its alleged respon-

sibility for monopoly, wars, and racism. He developed a social philosophy of capitalism which demonstrates the benevolent operation of all of capitalism's leading institutions, especially private ownership of the means of production, economic competition, and economic inequality. He expounded a procapitalist interpretation of modern economic history, and provided a devastating critique of socialism and government intervention in all of its forms. Above all, he demonstrated that a socialist economic system lacks the ability to engage in rational economic *planning* because of its lack of a price system and thus the ability to perform economic calculation. In making it possible for the more intelligent and honest members of Communist-bloc governments to understand the causes of the chaos and misery surrounding them, the writings of von Mises have played a major role in the growing worldwide efforts to abandon socialism. Nothing could be more deserved than if some of the statues of Lenin, now being removed all across Eastern Europe, were replaced with statues of this man, whose writings clearly proved the destructive consequences of socialism as far back as 1922. Indeed, statues should be erected to von Mises all across the world for saving it from socialism, and for his accomplishments in support of capitalism.

It is to von Mises, more than to any other single source, that this book is indebted. Indeed, the present book could accurately be described as "Misesianism" reinforced by a modernized, consistently procapitalist version of classical economics—it is the ideas of von Mises fused with insights derived from Ricardo and Smith.¹¹

Largely thanks to von Mises, there have been other important recent or contemporary advocates of capitalism. F. A. Hayek and Milton Friedman are the two leading examples. But, in my judgment, neither they nor anyone else begins to compare to von Mises in logical consistency and intellectual breadth and depth in the defense of capitalism. Hayek, for example, finds "a comprehensive system of social insurance" to be consistent with capitalism.¹² Friedman believes that fiat money is consistent with capitalism.

Other, lesser defenders of capitalism have even more serious inconsistencies. The so-called supply-siders—Robert Mundell, Arthur Laffer, and Jude Wanniski—apparently want to achieve capitalism without facing the need to reduce government spending and eliminate the welfare state. Much worse, Rothbard, who was widely regarded as the intellectual leader of the younger generation of the Austrian school and of the Libertarian party as well, was a self-professed anarchist and believed that *the United States was the aggressor against Soviet Rus-*

sia in the so-called cold war.¹³

By way of contrast, Henry Hazlitt, a brilliant economist and journalist, had the great merit of providing what are unquestionably the best introductions to the ideas of von Mises and the classical economists that exist.¹⁴ Hazlitt, incidentally, also shared with von Mises the honor of having expounded decades ago, as a virtual intellectual footnote to their major accomplishments, the legitimate substance of what has today become known as “the rational expectations approach”—namely, the recognition that economic phenomena such as interest rates incorporate expectations concerning inflation and thus defeat the objectives sought by the government’s policy of inflation.¹⁵

2. Pseudoeconomic Thought

Little or nothing is known about the state of economic knowledge that may have been achieved by the ancient Greeks and Romans. Some discussions of economic matters took place among scholastic philosophers in the Middle Ages, who appraised economic activity largely from the hostile perspective of the Roman Catholic church and who, accordingly, denounced as unjust such perfectly normal economic activities as the taking of interest on loans, speculation, and, indeed, even the mere changing of prices. The scholastics contributed nothing to sound economics.

The first prominent group of writers on economic subjects were the mercantilists, who appeared on the scene in the sixteenth and seventeenth centuries, following the great intensification of commerce and trade that had taken place subsequent to the end of the Dark Ages. The main concern of the mercantilists was with the so-called balance of trade and the alleged need of governments to secure an excess of exports over imports, as the means of increasing the quantity of money in a country that lacked its own gold and silver mines.¹⁶ The concern of the mercantilists with increasing the quantity of money led them to anticipate the essential fallacy of Lord Keynes in this century, namely, that it is necessary for the government to intervene in the economic system for the purpose of stimulating “demand” and “employment.” The leading members of the mercantilist school were Louis Bodin (1530–96), Thomas Mun (1571–1641), William Petty (1623–87), Josiah Child (1630–99), and the philosopher John Locke (1622–1704).

The positive economic truths later demonstrated by the classical and Austrian schools and their allies have been opposed from a number of quarters. In the first part of the nineteenth century, there were Malthus (1766–1834) and Sismondi (1773–1842) who, in anticipation of the Marxists and Keynesians, erroneously argued that

depressions were caused by overproduction and excess saving and underconsumption. (Malthus was also the author of the mistaken doctrine that increases in population necessarily tend to reduce the productivity of labor and the general standard of living—a doctrine that, apart from Adam Smith and Bastiat, was, regrettably, accepted by most of the classical economists.) In addition, there were the protectionists and the nationalists who, continuing to be committed to mercantilist ideas, attacked the classical economists’ doctrine of international free trade. Foremost in this group were Alexander Hamilton (1755–1804), who, of course, was the first American secretary of the treasury, and the German Friedrich List (1789–1848).

Fundamental opposition to classical and Austrian economics came from the German historical school, whose members denied the very possibility of a science of economic laws. This group included Wilhelm Roscher (1817–94), Gustav Schmoller (1838–1917), Lujo Brentano (1844–1931), and Werner Sombart (1863–1941). (Sombart, interestingly, began his career as a Marxist and later became a leading supporter of Nazism.) The essential approach of the German historical school was propounded in the United States by Thorstein Veblen (1857–1929), John R. Commons (1862–1945), and Wesley Mitchell (1874–1948), who are known as the American institutional school. The leading characteristic of these schools is a distrust of deductive logic (which is the essential method used in economics for arriving at knowledge), and thus opposition to economic theory as such. They deny the possibility of universally valid economic laws, claim that each country, in each historical period, has its own economic laws, and advance historical research, the study of economic institutions, and the gathering and study of economic statistics as the only legitimate means for arriving at economic knowledge.

The socialists, not surprisingly, are entirely opposed to the fundamental economic truths propounded by the classical and Austrian schools. (This is aside from the labor theory of value and the so-called iron law of wages, which they take over from classical economics and totally distort and twist into a form that the classical economists would not support.) The leading socialists, of course, were Karl Marx (1818–83) and Friedrich Engels (1820–97). Among their most important followers were Rosa Luxemburg (1870–1919) and Rudolf Hilferding (1877–1941). Other prominent socialists, prior to or contemporary with Marx, were Henri de Saint-Simon (1760–1825), Robert Owen (1771–1858), Charles Fourier (1772–1837), Louis Blanc (1811–82), Pierre Proudhon (1809–65), and Karl Rodbertus (1805–75). It should be noted that the socialists and the other opponents of the doctrines of the classical and Austrian schools substan-

tially overlap in their criticisms of capitalism. For example, virtually all of them share the belief that depressions are the result of “overproduction” and excess saving.

For want of a better place to classify him, mention must be made here of Henry George (1839–97), an American economist who developed certain half-truths of the classical school concerning land and land rent into a doctrine calling for the nationalization of land. Surprising as it may seem, in all other respects, George and most of his followers claim to be supporters of capitalism.¹⁷

Marshallian Neoclassical Economics: The Monopoly Doctrine and Keynesianism

In the present-day United States, the leading opposition within the economics profession to the ideas of the classical and Austrian schools, and to capitalism, derives from the ideas of a late-Victorian British neoclassical economist named Alfred Marshall (1842–1924), and two other figures associated with Britain’s Cambridge University and heavily influenced by the ideas of Marshall: John Maynard Keynes (1883–1946) and Mrs. Joan Robinson (1903–83). Marshall superficially accepted the concept of marginal utility while opposing the fundamental approach of the Austrian school. At the same time, he abandoned the fundamental ideas of the classical school while wrapping himself in the guise of the defender of classical economics against the criticisms of the Austrian school. The result of his work, his bequest to subsequent generations of economists, was a hodge-podge of confusions, which took the place of sound economics.

Both the classical and the Austrian schools study economic phenomena from the point of view of their effects on all members of the economic system, not just on those directly involved. In contrast, Marshall advanced the doctrine known as “partial equilibrium,” which is the attempt to study the behavior of individual consumers, individual firms, and individual industries divorced from the rest of the economic system. His approach was one of disintegration, resulting in the present-day existence of two allegedly separate branches of economics: “microeconomics” and “macroeconomics”—the first studying the actions of individuals apart from their relationship to the rest of the economic system, and the second studying the economic system as a whole, apart from the actions of individuals.

Marshall and his followers coupled the doctrine of partial equilibrium with a total confusion between the concepts of cost of production and supply, making it impossible to distinguish between cases in which prices are determined by supply and demand and cases in which, in the first instance, they are determined directly on the basis of cost of production. The result was the loss

of the knowledge gained by the classical economists (and recognized by Böhm-Bawerk and Wieser) that prices are in fact frequently determined in the first instance directly by cost of production. The result was also the inability to grasp the contribution of the Austrian school (substantially anticipated by John Stuart Mill) that the prices which constitute the costs of production are themselves always ultimately determined by supply and demand. It is Marshall’s confusions which underlie the widespread belief that economic law does not apply to the pricing of most manufactured or processed goods—that the prices of such goods are “administered prices,” precisely because they are determined directly on the basis of a consideration of cost of production rather than by the combination of demand and supply.

In propounding the doctrine of partial equilibrium, Marshall introduced the perverse concept of the “representative firm”—an alleged *average* firm, some multiple of which was supposed to constitute an industry. This concept destroyed economic theory’s ability to recognize even the possibility of competition. This was because if all firms in an industry were in fact perfectly equal, no basis could exist for any of them winning out in competition, or, therefore, for attempting to compete in the first place. Not surprisingly, the acceptance of the concept of the representative firm led some decades later to the conclusion (regarded at the time as a revolutionary discovery) that no reason existed for a sizable firm ever to cut its price, except in conditions in which it would pay a single-firm “monopoly” to do so. This was because its competitors, all of whom were supposed to be just as efficient as it was, would immediately match its cut. Thus, it would have little or nothing to gain by cutting—certainly not the business of its competitors.

The notion of the representative firm and the inability to see how cost of production normally acts as the direct determinant of the prices of manufactured or processed goods have served as the foundation for the widespread acceptance since the 1930s of the thoroughly malicious and destructive doctrine of Joan Robinson and Edward Chamberlin. That doctrine states that with a few, limited exceptions, such as wheat farming, the whole of a capitalist economic system is tainted by an element of monopoly. The solution for this alleged state of affairs is supposed to be a radical antitrust policy, which would fragment all large businesses, or else the nationalization of such businesses and/or government control over their prices—and further policies that would force firms in the same industry to produce identical, indistinguishable products. Since the 1930s, this doctrine and its elaboration have constituted the substance of the theoretical content of most textbooks of “microeconomics.” At the same time, little or nothing of the sound price theory

developed by the classical and Austrian economists is presented in these textbooks.

The abandonment of classical economics and Marshall's concentration on what later came to be called microeconomics created a temporary intellectual vacuum. In the 1930s, this vacuum was filled by Keynes, by means of the resurrection of the long-refuted fallacies of the Mercantilists, and Malthus and Sismondi, alleging that capitalism causes depressions and mass unemployment through overproduction and excess saving. On this thoroughly erroneous foundation, Keynes argued for the need for inflation and deficit-financed government spending to counteract or prevent the evils of depressions and mass unemployment. The elaboration of the Keynesian doctrines has constituted the theoretical substance of the textbooks on "macroeconomics."

Mathematical Economics

Another prominent school of economic thought is that of mathematical economics, which is characterized by the use of calculus and simultaneous differential equations to describe economic phenomena. The principal founder of mathematical economics was Léon Walras (1834–1910), a Swiss, who also independently discovered the law of diminishing marginal utility shortly after Menger and Jevons. Vilfredo Pareto (1848–1923), an Italian, succeeded Walras at the University of Lausanne and elaborated his approach.

Mathematical economics is fundamentally a matter more of method and pedagogy than of particular theoretical content. And although neither the classical nor the Austrian schools is mathematical in the above sense, there are mathematical economists who are allied with their teachings and their support of capitalism. Walras, Jevons, and Gossen are important cases in point.

Regrettably, the use of calculus and differential equations to describe economic phenomena represents a Procrustean bed, into which the discrete, discontinuous phenomena of actual economic life are mentally forced, in order to fit the mold of mathematically continuous functions to which the methods of calculus can be applied. This has consequences which represent a matter of theoretical content, as well as method.

One major consequence is the aid given to the perpetuation of a false theory of the determination of the prices of the factors of production: namely, the theory that the prices of the factors of production are directly derivable from the value of the consumers' goods they help to produce. For example, the wages of automobile workers, and the prices of auto-making equipment, steering wheels, brakes, spark plugs, and all other factors of production necessary to produce an automobile, are regarded as being derivable directly from the price of automobiles,

by means of calculating the loss in the value of an automobile that would accompany the withdrawal of a unit of any of the factors of production necessary to produce it.

Such a derivation of value, of course, must encounter the same difficulty as attempting to derive from the value of a pair of shoes a separate value for the right and left shoes—namely, the fact that the value of the combined product is capable of being alternatively attributed to *any* of the elements necessary to its production or enjoyment, and that on this basis the sum of the derived values of the factors of production must far exceed the value of the product. In the case of the shoes, for example, the loss of either shoe destroys the whole value of the pair. If the value of each shoe were derived by calculating the loss in value of the pair resulting from its removal, the sum of the value of the two shoes considered separately would be twice the value of the pair. In the case of the automobile, the entire value of the automobile would have to be attributed to each of many different components, such as each of the four wheels, the carburetor, the steering wheel, etc.

Mathematical economics creates the illusion that this problem can be solved by making believe that what are withdrawn are not discrete units of the factors of production, such as one whole shoe or one whole wheel, but infinitesimally small quantities of them. In this case, the loss in the value of the product could be regarded as a partial derivative of the reduction in the quantity of the factor of production, and the theorem would be applicable that the sum of the partial derivatives does not exceed, but is equal to the total derivative.

The area of a room, which is determined by the product of its length and width, can serve as an illustration. If the length of the room is ten feet and the width is ten feet, then the entire area of the room is lost if either the length or the width shrinks to zero. If one adopts the procedure of alternatively attributing to the length and the width the area that is lost when it is lost, then one would have to attribute a total of two hundred square feet of area lost, despite the fact that the actual area of the room is only one hundred square feet. If, however, one assumes that what is lost is not all of the length or, alternatively, all of the width, but only a small fraction of the length or width, then the difference between the sum of the two separate losses and the actual total loss diminishes. For example, if what is lost is one foot of length out of ten or, alternatively, one foot of width out of ten, the sum of the two separate areas lost is twenty square feet. The area lost by the simultaneous loss of a foot of length and width is nineteen square feet. Thus the difference between the sum of the two partial losses and the total loss has sharply diminished. It would approach

zero, as the reduction in length and width became smaller.

Unfortunately for this approach, the actual problem in the real world is how does one evaluate the effect of the loss of a whole shoe or wheel, not the tip of the shoelace or the effect of a scratch on the hubcap.

The result of such distortion of the actual problem is that mathematical economics has operated to conceal the true proposition, grasped by Ricardo and endorsed by Böhm-Bawerk and Wieser, that typically it is *not* the price of the product that determines the prices of the factors of production used to produce it, but the other way around. The price of automobiles and virtually all other manufactured or processed goods is determined on the basis of the wage rates, equipment prices, and parts prices that enter into their production. However, wage rates, which are the prices that most fundamentally determine costs of production, since they enter into every stage of production, are themselves determined by the supply of and demand for labor operating throughout the economic system. The same is true of the prices of the various raw materials whose supply cannot be immediately increased or decreased in response to changes in demand. The wage rates of the different types of labor relative to one another, above all the wages of skilled labor relative to those of unskilled labor, and the relative prices of such raw materials, reflect the relative marginal utilities of these factors of production in the economic system as a whole. Thus it is mainly in this *indirect* way that marginal utility operates to determine prices.¹⁸

A second and even more serious consequence of mathematical economics is that it leads to an undue concentration of attention on states of final equilibrium, which are all that its differential equations are capable of describing. It thus takes attention away from the real-world *operation* of the profit motive and of the *market processes* by means of which the economic system continually tends to move toward a state of full and final equilibrium without ever actually achieving such a state. The economic system never actually achieves such a state because of continuous changes in the fundamental economic data. For example, there are changes in the state of technology, changes in the size of population, changes in the relative valuation of the various consumers' goods, changes in the relative valuation of present enjoyment versus provision for the future, and numerous other such changes which occur continuously and which operate to change the final state of equilibrium toward which the economic system is tending.¹⁹

The effect of the dominance of mathematical economics and of the fact that it ignores market processes has been that all the major principles which explain how prices are actually determined, and which were discovered by the classical economists, have been virtually

forgotten. Among the principles lost have been recognition of the tendency toward a uniform rate of profit on capital invested throughout the economic system, recognition of the tendency toward the establishment of uniform prices for the same goods throughout the world and over time, and recognition of the tendency toward the establishment of uniform wage rates for labor of the same degree of skill and ability in the same market. These principles have virtually disappeared from contemporary economics textbooks.²⁰

Third, mathematical economics has come to serve as a mechanism for the erection of a sort of exclusive "Scholars' Guild," which, as was the case in the Middle Ages, seeks to shut out all who do not first translate their thoughts into its esoteric language. Higher mathematics is no more necessary to the discussion or clarification of economic phenomena than was Latin or Greek to the discussion of matters of scientific interest in previous centuries. One can, for example, say that the amount of bread people will buy at any given price of bread depends both on the price of bread and on the prices of all other goods in the economic system. Or one can say that the quantity demanded of bread is a mathematical function of all prices in the economic system, and then write out a nonspecific mathematical function using symbolic terminology.

If one merely writes such an equation and stops at this point, all that has taken place is an act of intellectual pretentiousness and snobbery—a translation into a present-day equivalent of Greek or Latin. If, however, one goes further, and believes one can actually formulate a *specific equation*—that, for example, the quantity demanded of bread equals ten thousand divided by half the square of the price of bread minus the price of butter and the average age of grocers, then one is led into major errors. This is so because no such equation can possibly hold up in the face of changes in the fundamental economic data. New goods are introduced. People's ideas and valuations change. Their real incomes change. Population changes. The belief that an equation could be constructed that would take such changes into account is totally opposed to reality. It is tantamount to a belief in fatalistic determinism and implies, in effect, that a mathematical economist can gain access to a book in which all things past, present, and future are written and then derive from it the corresponding equation. Whatever it may be, such a view is definitely not within the scientific spirit.

3. Overview of This Book

I have divided the present book into three major parts. Part 1, *The Foundations of Economics*, explains the

nature of economics and capitalism, including the role of a philosophy of reason in economic activity. It then shows that, based on his nature as a rational being, man possesses a limitless need for wealth. This, in turn, is shown to give rise to the central problem of economic life, which is how steadily to raise the productivity of human labor, that is, the quantity and quality of the goods that can be produced per unit of labor. Next, it is shown why the continuing rise in the productivity of labor is not prevented by any lack of natural resources, indeed, how man is capable of progressively enlarging the supply of useable, accessible natural resources as part of the very same process by which he increases the production of products. The part concludes with a lengthy critique of the ecology doctrine, which, it shows, represents a direct and major assault on the value of economic progress and thus on the very foundations of economics, and has replaced socialism as the leading threat to economic activity and economic progress.

Part 2, *The Division of Labor and Capitalism*, opens with a demonstration that the existence of a division-of-labor society is the essential framework for the ongoing solution of the problem of how continually to raise the productivity of labor. It then goes on to demonstrate that a division-of-labor society is a *capitalist* society, totally dependent on the operation of a price system, which in turn totally depends on private ownership of the means of production. Private ownership of the means of production is shown to be the foundation both of the profit motive and of the freedom of competition, which are respectively the driving force and regulator of the price system. This part, which incorporates almost all of my previously published *The Government Against the Economy*, develops all of the leading principles of price theory and applies them to understanding major events of the present and recent past.²¹ It clearly explains the factors leading to the collapse of socialism around the world and the destructive consequences of socialistic government intervention here in the United States in the form of price controls. It shows why, necessarily lacking a price system, socialism is necessarily chaotic economically and tyrannical politically. It shows how price controls were responsible for all aspects of the energy crisis of the 1970s and how they continue to threaten the long-term viability of major industries in the United States, such as electric power and rental housing.

Very importantly, this part explains the actual, benevolent nature of capitalism, in that it shows how the existence of the division of labor profoundly influences the operation of private ownership of the means of production, economic competition, and economic inequality, in ways that render these institutions thoroughly benevolent in their effects on the average person. In

essence, this part shows that beneath the division of labor it is capitalism that is the essential framework for economic progress and a rising productivity of labor, and that capitalism is characterized by a harmony of the rational self-interests of all men under freedom. The part also includes critiques of all forms of the doctrine that capitalism results in monopoly. It shows that monopoly, properly understood, is not a product of capitalism but is imposed on the economic system by government intervention. In addition, it includes an exhaustive critique of the Marxian exploitation theory. It shows that under capitalism there is no economic exploitation, that capitalists, far from exploiting wage earners and appropriating as profits what is rightfully wages, make it possible for people to live as wage earners, and to live ever more prosperously. It shows that this is because capitalists *create* wages and the demand for labor in tandem with reducing the share of sales proceeds which is profit, and go on steadily increasing the supply of goods that the wage earners can buy. It shows that socialism is the system both of the exploitation of labor and of universal monopoly.

Part 3, *The Process of Economic Progress*, centers on the explanation of the process of economic progress under capitalism. It explains the quantity theory of money and the essential role of the quantity of money in determining aggregate monetary demand, that is, total spending in the economic system. In full confirmation of Say's Law, it shows that in contrast to mere monetary demand, *real* demand—that is, actual purchasing power—is increased only by virtue of increases in the production and supply of goods. Along the same lines, it shows that real wages are increased essentially only by virtue of increases in the productivity of labor and thus increases in the supply of goods relative to the supply of labor. This part explains the vital role of capital accumulation in raising the productivity of labor and real wages. It explains the dependence of capital accumulation itself on saving, technological progress, and everything else that is necessary to economic efficiency, from freedom from government regulation at home to free trade abroad. It shows that the ultimate foundation of capital accumulation and economic progress is the existence of a capitalist society and its cardinal values of reason and freedom. Part 3 also explains the determinants of the average rate of profit and interest and the relationship between the rate of profit and interest, on the one side, and capital accumulation and falling prices caused by increased production, on the other side. It shows that capital accumulation and such falling prices do not reduce the rate of profit or interest and thus do not interfere with or retard the process of economic progress in any way.

This part contains refutations of all the leading economic fallacies concerning alleged overproduction, over-

saving, and underconsumption. Under this head, it includes a chapter-length refutation of the doctrines of Keynes and critiques of virtually all other fallacies underlying demands for inflation and government spending. The part makes a consistent case for a full-bodied gold standard as the ideal monetary system, which would exist under laissez-faire capitalism and which would operate to prevent inflation, deflation and depression, and mass unemployment. It shows that all of these destructive phenomena are caused by government intervention in the economic system, not by the nature of the economic system itself—that is, not by capitalism. It shows consistently that the establishment of economic freedom, of laissez-faire capitalism, is the solution for all such problems.

Finally, the Epilogue outlines a long-term political

and educational strategy for the achievement of a society of laissez-faire capitalism.

This book is useable as a textbook in virtually any economics course. Those who must conform to the arbitrary division of economics into microeconomics and macroeconomics will find that Chapters 1–10 can easily serve in the micro portion, while Chapters 11–19 can easily serve in the macro portion.²² Chapter 20, although best read after all of the other chapters, is suitable for use in either portion.

Use of this book in any economics course will provide the most efficient means both of advancing positive economic truth and of refuting the manifold errors in the prevailing views of economics, including those in the present generation of textbooks

Notes

1. For an excellent account of the doctrines of the Physiocrats, see Adam Smith, *The Wealth of Nations* (London, 1776), bk. 4, chap. 9; reprint of Cannan ed. (Chicago: University of Chicago Press, 2 vols. in 1, 1976), 2:182–209. From now on, specific page references to the University of Chicago Press reprint will be supplied in brackets.
2. The present author was also one of the later students of von Mises. However, because of the profound influence of the classical economists on my thinking, it would be more appropriate to describe my views as “Austro-classical” rather than as “Austrian.”
3. On the wages-fund doctrine and the consequences of its abandonment, see below pp. 664–666 and 864–867.
4. Smith, *Wealth of Nations*, bk. 1, chap. 4 [1:32–33].
5. For confirmation of this claim, see below, pp. 475–485. See also the whole of Chapter 14.
6. The contributions of James Mill are among the least recognized in the history of economic thought. Their best statement appears in his little known work *Commerce Defended* (London, 1808), chaps. 6 and 7, which are respectively titled “Consumption” and “Of the National Debt.” The complete work is reprinted in *James Mill Selected Economic Writings*, ed. Donald Winch (Chicago: University of Chicago Press, 1966).
7. Cf. below, pp. 414–416, where Böhm-Bawerk is quoted at length on this subject.
8. Strictly speaking, the consumption in question is what I term *net* consumption. See below, pp. 725–736.
9. See below, pp. 838–856.
10. See Eugen von Böhm-Bawerk, *Capital and Interest*, 3 vols., trans. George D. Huncke and Hans F. Sennholz (South Holland, Ill.: Libertarian Press, 1959), 2:168–176, 248–256; 3:97–115. See also John Stuart Mill, *Principles of Political Economy*, Ashley ed. (1909; reprint ed., Fairfield, N. J.: Augustus M. Kelley, 1976), pp. 442–468.
11. For a related description of the ideas of von Mises, see above, pp. xlii–xliii. The ideas of Böhm-Bawerk also play an important role.

12. See Friedrich A. Hayek, *The Road to Serfdom* (Chicago: University of Chicago Press, 1944), p. 121.
13. Cf. Murray N. Rothbard, *For a New Liberty* (New York: Macmillan, 1973). In that book, Rothbard wrote: “Empirically, the *most* warlike, *most* interventionist, *most* imperial government throughout the twentieth century has been the United States” (p. 287; italics in original). In sharpest contrast to the United States, which has supposedly been more warlike even than Nazi Germany, Rothbard described the Soviets in the following terms: “Before World War II, so devoted was Stalin to peace that he failed to make adequate provision against the Nazi attack. . . . Not only was there no Russian expansion whatever apart from the exigencies of defeating Germany, but the Soviet Union time and again leaned over backward to avoid any cold or hot war with the West” (p. 294).
14. See Henry Hazlitt, *Economics in One Lesson*, new ed. (New Rochelle, N. Y.: Arlington House, 1979); idem, *The Great Idea* (1951; rev. ed. published under the title *Time Will Run Back*, New Rochelle, N. Y.: Arlington House, 1966).
15. See Henry Hazlitt, “Is Inflation Necessary?” *Freeman* 2, no. 26 (September 22, 1952), pp. 880–882, and Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 776–777, 792–793. Amazingly, as an eloquent commentary on the state of contemporary economics, while the rational expectations approach has come to be regarded as a major and profound school of economic thought, the overwhelming merit of von Mises and the Austrian school still goes largely unrecognized. Thus, Samuelson and Nordhaus, in their self-proclaimed “authoritative” and “comprehensive” textbook include “Rational Expectations Macroeconomics” in their “Family Tree of Economics” and devote a full appendix to discussing it. Yet they make almost no mention of the Austrian school or von Mises; the Austrian school does not even appear in the index. See Paul Samuelson and William Nordhaus, *Economics*, 13th ed. (New York: McGraw-Hill, 1989), in particular the inside back cover. The leading members of the Rational Expectations school, incidentally, are Robert Barro, Robert Lucas,

Thomas Sargent, and Neil Wallace. (I wish to note that my references to Samuelson and Nordhaus throughout this work will be to the 13th edition rather than to the more recent 14th edition, unless otherwise stated. This is because it better represents the errors that two generations of students have had to endure at the hands of Prof. Samuelson, who, until not many years ago, was the sole author.)

16. For an exposition and critique of the doctrines of the Mercantilists, see Adam Smith, *Wealth of Nations*, bk. 4, chaps. 1–8 [2:3–209]. See also below, pp. 526–536.

17. In private conversation with the present author, Leonard Peikoff once aptly described the position of the Georgists as advocating the government allowing a person to own a piano and do anything he likes with it, except put it down without its permission.

18. For elaboration of these points, see below, the discussions of the relationship between prices and costs on pp. 200–201, 206–209, and 411–417.

19. Cf. von Mises, *Human Action*, pp. 244–250.

20. For an explanation of these principles, see below, pp. 172–201.

21. George Reisman, *The Government Against the Economy* (Ottawa, Ill.: Jameson Books, 1979). A few pages of this book, which demonstrate the limitless potential of natural resources, are incorporated in Chapter 3.

22. Logically, Chapter 11 belongs in Part 2, where it is. Nevertheless, from the point of view of the division of economics into “microeconomics” and “macroeconomics,” the chapter is far more essential in a course on the latter than in one on the former.

PART ONE
THE FOUNDATIONS OF ECONOMICS

CHAPTER 1

ECONOMICS AND CAPITALISM

PART A

THE NATURE AND IMPORTANCE OF ECONOMICS

1. Economics, the Division of Labor, and the Survival of Material Civilization

Economics has been defined in a variety of ways. In the nineteenth century it was typically defined as the science of wealth or of exchangeable wealth. In the twentieth century, it has typically been defined as the science that studies the allocation of scarce means among competing ends.¹

I define economics as *the science that studies the production of wealth under a system of division of labor*, that is, under a system in which the individual lives by producing, or helping to produce, just one thing or at most a very few things, and is supplied by the labor of others for the far greater part of his needs. The justification of this definition will become increasingly clear as the contents of this book unfold.²

The importance of economics derives from the specific importance of wealth—of material goods—to human life and well-being. The role of wealth in human life is a subject that will be examined in Chapter 2 of this book, but provisionally its importance can be accepted on a common-sense basis. Obviously, human life depends on food, clothing, and shelter. Moreover, experience shows that there is no limit to the amount of wealth that practi-

cally all civilized men and women desire, and that the greatest part of their waking hours is actually spent in efforts to acquire it—namely, in efforts to earn a living.

Yet the importance of wealth, by itself, is not sufficient to establish the importance of economics. Robinson Crusoe on a desert island would need wealth, and his ability to produce it would be helped if he somehow managed to salvage from his ship books on various techniques of production. But it would not be helped by books on economics. All that books on economics could do for Crusoe would be to describe abstractly the essential nature of the activities he carries on without any knowledge of economics, and, beyond that, merely to provide the possible intellectual stimulation he might feel as the result of increasing his knowledge of the society from which he was cut off. Something more than the importance of wealth is required to establish the importance of economics.

As Chapter 4 of this book will show, the production of wealth vitally depends on the division of labor. The division of labor is an essential characteristic of every advanced economic system. It underlies practically all of the gains we ascribe to technological progress and the use of improved tools and machinery; its existence is indispensable for a high and rising productivity of labor, that is, output per unit of labor. By the same token, its absence is a leading characteristic of every backward economic system. It is the division of labor which introduces a degree of complexity into economic life that makes necessary the existence of a special science of economics. For the division of labor entails economic

phenomena existing on a scale in space and time that makes it impossible to comprehend them by means of personal observation and experience alone. Economic life under a system of division of labor can be comprehended only by means of an organized body of knowledge that proceeds by deductive reasoning from elementary principles. This, of course, is the work of the science of economics. The division of labor is thus the essential fact that necessitates the existence of the subject of economics.³

Despite its vital importance, the division of labor, as a country's dominant form of productive organization—that is, a division-of-labor society—is a relatively recent phenomenon in history. It goes back no further than eighteenth-century Britain. Even today it is limited to little more than the United States, the former British dominions, the countries of Western Europe, and Japan. The dominant form of productive organization in most of the world—in the vast interiors of Asia, Africa, and most of Latin America—and everywhere for most of history, has been the largely self-sufficient production of farm families and, before that, of tribes of nomads or hunters.

What makes the science of economics necessary and important is the fact that while human life and well-being depend on the production of wealth, and the production of wealth depends on the division of labor, *the division of labor does not exist or function automatically*. Its functioning crucially depends on *the laws and institutions* countries adopt. A country can adopt laws and institutions that make it possible for the division of labor to grow and flourish, as the United States did in the late eighteenth century. Or it can adopt laws and institutions that prevent the division of labor from growing and flourishing, as is the case in most of the world today, and as was the case everywhere for most of history. Indeed, a country can adopt laws and institutions that cause the division of labor to decline and practically cease to exist. The leading historical example of this occurred under the Roman Empire in the third and fourth centuries of the Christian era. The result was that the relatively advanced economic system of the ancient world, which had achieved a significant degree of division of labor, was replaced by feudalism, an economic system characterized by the self-sufficiency of small territories.⁴

In order for a country to act intelligently in adopting laws and institutions that bear upon economic life, it is clearly necessary that its citizens understand the principles that govern the development and functioning of the division of labor, that is, understand the principles of economics. If they do not, then it is only a question of time before that country will adopt more and more destructive laws and institutions, ultimately stopping all further economic progress and causing actual economic

decline, with all that that implies about the conditions of human life.

In the absence of a widespread, serious understanding of the principles of economics, the citizens of an advanced, division-of-labor society, such as our own, are in a position analogous to that of a crowd wandering among banks of computers or other highly complex machinery, with no understanding of the functioning or maintenance or safety requirements of the equipment, and randomly pushing buttons and pulling levers. This is no exaggeration. In the absence of a knowledge of economics, our contemporaries feel perfectly free to enact measures such as currency depreciation and price controls. They feel free casually to experiment with the destruction of such fundamental economic institutions as the freedom of contract, inheritance, and private ownership of the means of production itself. In the absence of a knowledge of economics, our civilization is perfectly capable of destroying itself, and, in the view of some observers, is actually in the process of doing so.

Thus, the importance of economics consists in the fact that ultimately our entire modern material civilization depends on its being understood. What rests on modern material civilization is not only the well-being but also *the very lives* of the great majority of people now living. In the absence of the extensive division of labor we now possess, the production of modern medicines and vaccines, the provision of modern sanitation and hygiene, and the production even of adequate food supplies for our present numbers, would simply be impossible. The territory of the continental United States, for example, counting the deserts, mountains, rivers, and lakes, amounts to less than nine acres per person with its present population—not enough to enable that population to survive as primitive farmers. In Western Europe and Japan, the problem of overpopulation would, of course, be far more severe. Needless to say, the present vast populations of Asia, Africa, and Latin America would be unable to survive in the absence of Western food and medical supplies.

2. Further Major Applications of Economics

Solving Politico-Economic Problems

Apart from the very survival of a division-of-labor society, and all that depends on it, the most important application of economics is to provide the knowledge necessary for the adoption of government policies conducive to the smooth and efficient functioning of such a society.⁵ On the basis of the knowledge it provides, economics offers logically demonstrable solutions for politico-economic problems. For example,

it explains very clearly how to stop such major present-day problems as inflation, shortages, depressions, and mass unemployment, and how to turn capital decumulation into capital accumulation and a declining productivity of labor into a rising productivity of labor. In addition, economics can very clearly show how to achieve economic progress all across the world, and is potentially capable of playing an enormous role in eliminating the intellectual and economic causes both of domestic strife and of international conflict and war. As I will show, the essential nature of the policies economics demonstrates to be necessary to solve all such problems is respect for property rights and economic freedom.

Understanding History

Because it explains what promotes and what impairs the functioning of the division of labor, economics is an essential tool for understanding the world's history—the broad sweep of its periods of progress and its periods of decline—and the journalistic events of any given time. Its applications include a grasp of the causes of the decline of ancient civilization and of the rise of the modern, industrial world, both of which can be understood in terms of the rise or fall of the division of labor.

Economics brings to the understanding of history and journalism a foundation of scientific knowledge which can serve historians and journalists in much the same way as a knowledge of natural science and mathematics. Namely, it can give to historians and journalists a knowledge of what is and is not possible, and therefore a knowledge of what can and cannot qualify as an explanation of economic phenomena. For example, a knowledge of modern natural science precludes any historical or journalistic explanation of events based on Ptolemaic astronomy or the phlogiston theory of chemistry, not to mention beliefs in such notions as witchcraft, astrology, or any form of supernaturalism. In exactly the same way, it will be shown in this book that a knowledge of economics precludes any historical or journalistic explanation of events based on such doctrines as the Marxian theory of exploitation and class warfare, or on the belief that machinery causes unemployment or that depressions are caused by “overproduction.”⁶

Economics can also serve historians and journalists as a guide to what further facts to look for in the explanation of economic events. For example, whenever shortages exist, it tells them to look for government controls limiting the rise in prices; whenever unemployment exists, it tells them to look for government interference limiting the fall in money wage rates; and whenever a depression exists, it tells them to look for a preceding expansion of money and credit.⁷

Implications for Ethics and Personal Understanding

Economics has powerful implications for ethics. It demonstrates exhaustively that in a division-of-labor, capitalist society, one man's gain is not another man's loss, that, indeed, it is actually other men's *gain*—especially in the case of the building of great fortunes. In sum, economics demonstrates that the rational self-interests of all men are harmonious. In so doing, economics raises a leading voice against the traditional ethics of altruism and self-sacrifice. It presents society—a division-of-labor, capitalist society—not as an entity over and above the individual, to which he must sacrifice his interests, but as an indispensable means within which the individual can fulfill the ultimate ends of his own personal life and happiness.⁸

A knowledge of economics is indispensable for anyone who seeks to understand his own place in the modern world and that of others. It is a powerful antidote to unfounded feelings of being the victim or perpetrator of “exploitation” and to all feelings of “alienation” based on the belief that the economic world is immoral, purposeless, or chaotic. Such unfounded feelings rest on an ignorance of economics.

The feelings pertaining to alleged exploitation rest on ignorance of the productive role of various economic functions, such as those of businessman and capitalist, retailing and wholesaling, and advertising and speculation, and on the underlying conviction that essentially only manual labor is productive and is therefore the only legitimate form of economic activity.⁹ Feelings pertaining to the alleged purposelessness of much of economic activity rest on ignorance of the role of wealth in human life beyond the immediate necessities of food, clothing, and shelter. This ignorance leads to the conviction that economic activity beyond the provision of these necessities serves no legitimate purpose.¹⁰ Feelings pertaining to the alleged chaos of economic activity rest on ignorance of the knowledge economics provides of the benevolent role of such institutions as the division of labor, private ownership of the means of production, exchange and money, economic competition, and the price system.

In opposition to feelings of alienation, economic science makes the economic world fully intelligible. It explains the foundations of the enormous economic progress which has taken place in the “Western” world over the last two centuries. (This includes the rapid economic progress that has been made in recent decades by several countries in the Far East, which have largely become “Westernized.”) And in providing demonstrable solutions for all of the world's major economic problems, it points the way for intelligent action to make possible radical and progressive improvement in the material conditions of human beings everywhere. As a result, knowledge of the subject cannot help but support the conviction that the fundamental nature of the world is

benevolent and thus that there is no rational basis for feelings of fundamental estrangement from the world.¹¹

The above discussion, of course, is totally in opposition to the widely believed claims of Marx and Engels and their followers, such as Erich Fromm, that the economic system of the modern world—capitalism—is the basis of alienation. Indeed, it is consistent with the above discussion that the actual basis of “alienation” resides within the psychological makeup of those who experience the problem. Ignorance of economics reinforces feelings of alienation and allows the alleged deficiencies of the economic system to serve as a convenient rationalization for the existence of the problem.¹²

Economics and Business

Despite popular beliefs, economics is not a science of quantitative predictions. It does not provide reliable information on such matters as what the price of a common stock or commodity will be in the future, or what the “gross national product” will be in the next year or quarter.¹³

However, a knowledge of economics does provide an important intellectual framework for making business and personal financial decisions. For example, a businessman who understands economics is in a far better position to appreciate what the demand for his firm’s products depends on than a businessman who does not. Similarly, an individual investor who understands economics is in a vastly better position to protect himself from the consequences of such things as inflation or deflation than one who does not.

But the most important application of economics to business and investment is that only a widespread knowledge of economics can assure the continued existence of the very activities of business and investment. These activities are prohibited under socialism. In a socialist society, such as that of the former Soviet Union, which is governed by the belief that profits and interest are incomes derived from “exploitation,” individuals who attempt to engage in business or investment activity have been sent to concentration camps or executed. Business activities can endure and flourish only in a society which understands economics and which is therefore capable of appreciating their value. The value of economics to businessmen should be thought of not as teaching them how to make money (which is a talent that they possess to an incalculably greater degree than economists), but as explaining why it is to the self-interest of everyone that businessmen should be *free* to make money. This is something which businessmen do not know, which is vital to them (and to everyone else), and which economics is uniquely qualified to explain.

Economics and the Defense of Individual Rights

Knowledge of economics is indispensable to the defense of individual rights. The philosophy of individual rights, as set forth in the writings of John Locke and the Declaration of Independence and Constitution of the United States, has been thoroughly undermined as the result of the influence of wrong economic theories, above all, the theories of Karl Marx and the other socialists. The essential conclusion of such theories is that in the economic sphere the exercise of individual rights as understood by Locke and the Founding Fathers of the United States serves merely to enable the capitalists to exploit the workers and consumers, or is otherwise comparably destructive to the interests of the great majority of people. Precisely as a result of the influence of these vicious ideas, culminating in the victory of the New Deal, the Supreme Court of the United States has, since 1937, simply abandoned the defense of economic freedom. Since that time it has allowed Congress and the state legislatures, and even unelected regulatory agencies, to do practically anything they wish in this area, the Constitution and Bill of Rights and all prior American legal precedent notwithstanding.¹⁴

A thorough knowledge of economics is essential to understanding why the exercise of individual rights in the economic sphere not only is not harmful to the interests of others, but is in the foremost interest of everyone. It is essential if the American people are ever to reclaim the safeguards to economic freedom provided by their Constitution, or if people anywhere are to be able to establish and maintain systems of government based on meaningful respect for individual rights. Indeed, in demonstrating the harmony of the rational self-interests of all men under freedom, this entire book has no greater or more urgent purpose than that of helping to uphold the philosophy of individual rights.

The nature and importance of economics imply that study of the subject should be an important part of the general education of every intelligent person. Economics belongs alongside mathematics, natural science, history, philosophy, and the humanities as an integral part of a liberal education. It deserves an especially prominent place in the education of lawyers, businessmen, journalists, historians, the writers of literary works, and university, college, and secondary-school teachers of the humanities and social sciences. These are the groups that play the dominant role in forming people’s attitudes concerning legislation and social institutions and whose work can most profit from an understanding of economics.

PART B

CAPITALISM

This book shows that the laws and social institutions necessary to the successful functioning, indeed, to the very existence, of the division of labor are those of *capitalism*. Capitalism is a social system based on private ownership of the means of production. It is characterized by the pursuit of material self-interest under freedom and it rests on a foundation of the cultural influence of reason. Based on its foundations and essential nature, capitalism is further characterized by saving and capital accumulation, exchange and money, financial self-interest and the profit motive, the freedoms of economic competition and economic inequality, the price system, economic progress, and a harmony of the material self-interests of all the individuals who participate in it.

As succeeding chapters of this book will demonstrate, almost every essential feature of capitalism underlies the division of labor and several of them are profoundly influenced by it in their own operation. When the connections between capitalism and the division of labor have been understood, it will be clear that economics, as the science which studies the production of wealth under a system of division of labor, is actually the science which studies the production of wealth under *capitalism*. Economics' study of the consequences of government intervention and of socialism will be shown to be merely study of the impairment or outright destruction of capitalism and the division of labor.

1. The Philosophical Foundations of Capitalism and Economic Activity

Economic activity and the development of economic institutions do not take place in a vacuum. They are profoundly influenced by the fundamental philosophical convictions people hold.¹⁵ Specifically, the development of capitalist institutions and the elevation of the level of production to the standard it has reached over the last two centuries presuppose the acceptance of a *this-worldly, proreason philosophy*. Indeed, in their essential development, the institutions of capitalism and the economic progress that results represent the implementation of *man's right to life*, as that right has been described by Ayn Rand—namely, as the right “to take all the actions required by the nature of a rational being for the support, the furtherance, the fulfillment and the enjoyment of his own life.”¹⁶ Capitalism is the economic system that develops insofar as people are free to exercise their right to life and choose to exercise it. As will be shown, its

institutions represent, in effect, a self-expanded power of human reason to serve human life.¹⁷ The growing abundance of goods that results is the material means by which people further, fulfill, and enjoy their lives. The philosophical requirements of capitalism are identical with the philosophical requirements of the recognition and implementation of man's right to life.

It was no accident that the gradual development of capitalist institutions in Western Europe that began in the late Middle Ages paralleled the growing influence of prosecular, proreason trends in philosophy and religion, which had been set in motion by the reintroduction into the Western world of the writings of Aristotle. It is no accident that the greatest era of capitalist development—the last two centuries—has taken place under the ongoing cultural influence of the philosophy of the Enlightenment.

Philosophical convictions pertaining to the reality and primacy of the material world of sensory experience determine the extent to which people are concerned with this world and with improving their lives in it. When, for example, people's lives were dominated by the idea that the material world is superseded by another, higher world, for which their life in this world is merely a test and a preparation, and in which they will spend eternity, they had little motive to devote much thought and energy to material improvement. It was only when the philosophical conviction grew that the senses are valid and that sensory perception is the only legitimate basis of knowledge, that they could turn their full thought and attention to this world. This change was an indispensable precondition of the development of the pursuit of material self-interest as a leading force in people's lives.

The cultural acceptance of the closely related philosophical conviction that the world operates according to definite and knowable principles of cause and effect is equally important to economic development. This conviction, largely absent in the Dark Ages, is the indispensable foundation of science and technology. It tells scientists and inventors that answers exist and can be found, if only they will keep on looking for them. Without this conviction, science and technology could not be pursued. There could be no quest for answers if people were not first convinced that answers can be found.

In addition to the emphasis on this-worldly concerns and the grasp of the principle of cause and effect, the influence of reason shows up in the development of the individual's conceptual ability to give a sense of present reality to his life in decades to come, and in his identification of himself as a self-responsible causal agent with the power to improve his life. This combination of ideas is what produced in people such attitudes as the realization that hard work pays and that they must accept responsibility for their future by means of saving. The

same combination of ideas helped to provide the intellectual foundation for the establishment and extension of private property rights as incentives to production and saving. Private property rights rest on the recognition of the principle of causality in the form that those who are to implement the causes must be motivated by being able to benefit from the effects they create. They also rest on a foundation of secularism—of the recognition of the rightness of being concerned with material improvement.

Thus, insofar as production depends on people's desire to improve their material conditions, and on science, technology, hard work, saving, and private property, it fundamentally depends on the influence of a this-worldly, proreason philosophy.

And to the extent that production depends on peace and tranquility, on respect for individual rights, on limited government, economic and political freedom, and even on personal self-esteem, it again fundamentally depends on the influence of a this-worldly, proreason philosophy.

From the dawn of the Renaissance to the end of the nineteenth century, the growing conviction that reason is a reliable tool of knowledge and means of solving problems led to a decline in violence and the frequency of warfare in Western society, as people and governments became increasingly willing to settle disputes by discussion and persuasion, based on logic and facts. This was a necessary precondition of the development of the incentive and the means for the stepped-up capital accumulation required by a modern economic system. For if people are confronted with the chronic threat of losing what they save, and again and again do lose it—whether to local robbers or to marauding invaders—they cannot have either the incentive or the means to accumulate capital.

During the same period of time, as part of the same process, a growing confidence in the reliability and power of human reason led to the elevation of people's view of man, as the being distinguished by the possession of reason. Because he was held to possess incomparably the highest and best means of knowledge, man came to be regarded, on philosophical grounds, as incomparably the highest and best creature in the natural order, capable of action on a grand and magnificent scale, with unlimited potential for improvement. In conjunction with the further philosophical conviction that what actually exist are always individual concretes, not abstractions as such, and thus not collectives or groups of any kind, the elevated view of man meant an elevated view of *the individual human being* and his individual potential.

In their logically consistent form, these ideas led to a view of the individual as both supremely valuable—as

an end in himself—and as fully competent to run his own life. The application, in turn, of this view of the individual to society and politics was the doctrine of inalienable individual rights, and of government as existing for no other purpose than to secure those rights, in order to leave the individual free to pursue his own happiness. This, of course, was the foundation of the freedom of capitalism. The same view of man and the human individual, when accepted as a personal standard to be lived up to, was the inspiration for individuals to undertake large-scale accomplishments and to persevere against hardship and failure in order to succeed. It inspired them when they set out to explore the world, discover laws of nature, establish a proper form of government, invent new products and methods of production, and build vast new businesses and brand new industries. It was the inspiration for the pioneering spirit and sense of self-reliance and self-responsibility which once pervaded American society at all levels of ability, and a leading manifestation of which is the spirit of great entrepreneurship.

Finally, the ability of economic science itself to influence people's thinking so that they will favor capitalism and sound economic policy is also totally dependent on the influence of a proreason philosophy. Economics is a science that seeks to explain the complexities of economic life through a process of abstraction and simplification. The method of economics is the construction of deliberately simplified cases, which highlight specific economic phenomena and make possible a conceptual analysis of their effects. For example, in analyzing the effects of improvements in machinery, an economist imagines a hypothetical case in which no change of any kind takes place in the world except the introduction of an improved machine. The truths established deductively in the analysis of such cases are then applied as principles to the real economic world. Consequently, the ability of economics to affect people's attitudes depends on their willingness to follow and feel bound by the results of abstract reasoning. If economics is to have cultural influence, it is indispensable that people have full confidence in logic and reason as tools of cognition.

Not only are economic activity and economics as a science dependent on a proreason philosophy in all the ways I have described, but also it should be realized that economics itself is a highly philosophical subject, potentially capable of exerting an extremely important proreason influence on philosophy. As the subject that studies the production of wealth under a system of division of labor, economics deals both with essential aspects of man's relationship to the physical world and with essential aspects of his relationship to other men. Indeed, the subject matter of economics can be understood as noth-

ing less than the fundamental nature of human society and the ability of human beings living in society progressively to enlarge the benefits they derive from the physical world. For this is what one understands when one grasps the nature and ramifications of the division of labor and its effects on the ability to produce. In this capacity, economics overturns such irrationalist philosophical doctrines as the notion that one man's gain is another man's loss, and the consequent belief in the existence of an inherent conflict of interests among human beings. In their place it sets the doctrine of continuous economic progress and the harmony of the rational self-interests of all human beings under capitalism, which doctrine it conclusively proves on the basis of economic law.

2. Capitalism and Freedom

Freedom means *the absence of the initiation of physical force*. Physical force means injuring, damaging, or otherwise physically doing something to or with the person or property of another against his will. The *initiation* of physical force means starting the process—that is, being the first to use physical force. When one has freedom, what one is free of or free from is the initiation of physical force by other people. An individual is free when, for example, he is free from the threat of being murdered, robbed, assaulted, kidnapped, or defrauded.

(Fraud represents force, because it means taking away property against the will of its owner; it is a species of theft. For example, if a bogus repairman takes away a washing machine to sell it, while saying that he is taking it to repair it, he is guilty of force. In taking it to sell, he takes it against the will of the owner. The owner gives him no more authorization to sell it than he gives to a burglar.)

Freedom and Government

The existence of freedom requires the existence of government. Government is the social institution whose proper function is to protect the individual from the initiation of force. Properly, it acts as the individual's agent, to which he delegates his right of self-defense. It exists to make possible an organized, effective defense and deterrent against the initiation of force. Also, by placing the use of defensive force under the control of objective laws and rules of procedure, it prevents efforts at self-defense from turning into aggression. If, for example, individuals could decide that their self-defense required that they drive tanks down the street, they would actually be engaged in aggression, because they would put everyone else in a state of terror. Control over all use of force, even in self-defense, is necessary for people to be secure against aggression.¹⁸

An effective government, in minimizing the threat of aggression, establishes the existence of the individual's freedom in relation to all other private individuals. But this is far from sufficient to establish freedom as a general social condition. For one overwhelming threat to freedom remains: namely, aggression by the government itself.

Everything a government does rests on the use of force. No law actually is a law unless it is backed by the threat of force. So long as what the government makes illegal are merely acts representing the initiation of force, it is the friend and guarantor of freedom. But to whatever extent the government makes illegal acts that do not represent the initiation of force, it is the enemy and violator of freedom. In making *such* acts illegal, it becomes the initiator of force.

Thus, while the existence of freedom requires the existence of government, it requires the existence of a very specific kind of government: namely, a *limited* government, a government limited exclusively to the functions of defense and retaliation against the initiation of force—that is, to the provision of police, courts, and national defense.¹⁹

In a fully capitalist society, government does not go beyond these functions. It does not, for example, dictate prices, wages, or working conditions. It does not prescribe methods of production or the kinds of products that can be produced. It does not engage in any form of "economic regulation." It neither builds houses nor provides education, medical care, old-age pensions, or any other form of subsidy. All economic needs are met privately, including the need for charitable assistance when it arises. The government's expenditures are accordingly strictly limited; they do not go beyond the payment of the cost of the defense functions. And thus taxation is strictly limited; it does not go beyond the cost of the defense functions.²⁰

In short, in its logically consistent form, capitalism is characterized by *laissez faire*. The government of such a society is, in effect, merely a night watchman, with whom the honest, peaceful citizen has very little contact and from whom he has nothing to fear. The regulations and controls that exist in such a society are not regulations and controls on the activities of the peaceful citizen, but on the activities of common criminals and on the activities of government officials—on the activities of the two classes of men who use physical force. Under capitalism, while the government controls the criminals, it itself is controlled (as it was for most of the history of the United States) by a Constitution, Bill of Rights, and system of checks and balances achieved through a division of powers. And thus the freedom of the individual is secured.²¹

Given the existence of government and its power to restrain the private use of force, the concept of freedom must be defined in a way that places special stress on the relationship of the citizen to his government. This is because the government's capacity for violating freedom is incomparably greater than that of any private individual or gang whose aggression it fights. One has only to compare the Gestapo or the KGB with the Mafia, to realize how much greater is the potential danger to freedom that comes from government than from private individuals. The government operates through open lines of communication and has at its disposal entire armies that in modern times are equipped with artillery, tanks, planes, rockets, and atomic weapons. Private gangs number comparative handfuls of individuals, operating clandestinely and equipped at most perhaps with submachine guns. Thus, freedom must be defined not merely as the absence of the initiation of physical force, but, in addition, in order to highlight its most crucial aspect, the absence of the initiation of physical force by, or with the sanction of, *the government*. The very existence of government can easily secure the freedom of the individual in relation to all other private citizens. The crucial matter is the individual's freedom in relation to the government.

Freedom as the Foundation of Security

It is important to realize that freedom is the foundation of both personal and economic security.

The existence of freedom directly and immediately establishes personal security in the sense of safety from the initiation of physical force. When one is free, one is safe—secure—from common crime, because what one is free of or free from is precisely the initiation of physical force.

The fact that freedom is the absence of the initiation of physical force also means that *peace* is a corollary of freedom. Where there is freedom, there is peace, because there is no use of force: insofar as force is not initiated, the use of force in defense or retaliation need not take place. Peace in this sense is one of the most desirable features of freedom. Nothing could be more valuable or honorable.

There is, however, a different sense in which peace of some sort can exist. Here, one person or group threatens another with the initiation of force and the other offers no resistance, but simply obeys. This is the peace of slaves and cowards. It is the kind of peace corrupt intellectuals long urged on the relatively free people of the Western world in relation to the aggression of the Communist world.

Freedom is the precondition of economic security, along with personal safety, because it is an essential requirement for individuals being able to act on their rational judgment. When they possess freedom, individ-

uals can consider their circumstances and then choose the course of action that they judge to be most conducive to their economic well-being and thus to their economic security. In addition, they can benefit from the like choices of those with whom they deal.

Under freedom, everyone can choose to do whatever he judges to be most in his own interest, without fear of being stopped by the physical force of anyone else, so long as he himself does not initiate the use of physical force. This means, for example, that he can take the highest paying job he can find and buy from the most competitive suppliers he can find; at the same time, he can keep all the income he earns and save as much of it as he likes, investing his savings in the most profitable ways he can. The only thing he cannot do is use force himself. With the use of force prohibited, the way an individual increases the money he earns is by using his reason to figure out how to offer other people more or better goods and services for the same money, since this is the means of inducing them voluntarily to spend more of their funds in buying from him rather than from competitors. Thus, freedom is the basis of everyone being as secure as the exercise of his own reason and the reason of his suppliers can make him.

The detailed demonstration of the fact that economic freedom is the foundation of economic security is a major theme of this book. This book will show, for example, that free competition is actually a leading source of economic security, rather than any kind of threat to it, and that such phenomena as inflation, depressions, and mass unemployment—the leading causes of economic insecurity—are results of *violations of economic freedom by the government*, and not at all, as is usually believed, of economic freedom itself.²²

The harmony between freedom and security that this book upholds is, of course, in direct opposition to the prevailing view that in order to achieve economic security, one must violate economic freedom and establish a welfare state. The existence of the social security system, in the United States and other countries, both represents a leading consequence of this mistaken belief and provides essential evidence about what is wrong with it.

In the name of economic security, the freedom of individuals to dispose of their own incomes has been violated as they have been forced to contribute to the social security system. A major consequence of this has been that an enormous amount of savings has been diverted from private individuals into the hands of the government. Had these savings remained in the possession of the individuals, they would have been invested and would thus have helped to finance the construction and purchase of new housing, new factories, and more

and better machinery. In the hands of the government, these savings have been dissipated in current consumption. This has resulted from the fact that the government has an overwhelmingly greater interest in its own immediate financial needs than in the future economic security of any private individuals and thus has spent the funds in financing its current expenditures. This has meant the dissipation of these savings and thus the serious undermining of the wealth and productive ability of the entire economic system.²³

These results have proceeded from the essential nature of the case, which is that while private individuals have an interest in their long-run future economic security, and will provide for it if they are left free to do so, the government does not have such an interest. The interest of government officials is to get by in their term of office and leave the problems of the future to their successors. Thus the violation of economic freedom necessarily results in making individuals less economically secure. Indeed, having been deprived of the existence of actual savings to provide for their future economic security, individuals are now in the position of having to depend on the largesse of future legislators, who will have to turn to future taxpayers for the necessary funds. This arrangement has much more in common with the gross insecurity of living as a beggar than it has with any actual economic security.²⁴

In opposition to all such delusions, this book shows that to achieve economic security, the essential requirement is precisely economic freedom.

The Indivisibility of Economic and Political Freedom

Although the emphasis of this book is necessarily on the importance of economic freedom, this fact should not be taken in any way to mean a lack of concern for political freedom. Economic freedom and political freedom are indivisible. They are, in fact, merely different aspects of the same thing. The alleged dichotomy between economic freedom and political freedom, between property rights and human rights, is groundless. Virtually every human activity employs wealth—property. To respect the right and freedom to use property is to respect the right and freedom to carry on the activities in which property is used. To deny the right and freedom to carry on such activities is to deny the right and freedom to use the property involved.

For example, the freedom of speech is implied in a farmer's right to use his pasture as he sees fit. The farmer's property rights include his right to invite people onto his land to deliver and or hear a speech. Any effort by the government to stop or prevent such a speech is an obvious interference with the farmer's property rights.

Property rights also include the right to build meeting halls and radio and television stations and to use them to propound whatever ideas one likes. Freedom of speech is fully contained in the economic freedom of the owners of property of the kind that facilitates speech to use their property as they see fit. By the same token, the freedom of speech of those who do not own such property is implied in their right and freedom to buy the use of such property from those who do own it and are willing to rent it to them. Government interference with any such speech is simultaneously an interference with the property rights of the owners of meeting halls or radio or television stations to use or rent their facilities as they see fit.

In the same way, freedom of the press is fully contained in the freedom of an individual to set his type to form the words he wants to form, and then to use his presses, paper, and ink to reproduce those words, and to sell the resulting product to buyers of his choice. Freedom of travel is contained in the property right to build railroads and highways, automobiles and airplanes, to drive one's automobile where one likes, or buy a bus, train, or plane ticket from any willing seller. It is contained in the freedom to use one's shoes to walk across the frontier.

In prohibiting the freedom of speech, press, or travel, one prohibits property owners from using their property as they wish. By the same token, in respecting property rights, one respects these freedoms. On this basis, one should observe the irony of alleged conservative defenders of property rights advocating such things as antipornography legislation—a violation of the property rights of press owners—and of alleged liberal defenders of civil liberties advocating the violation of property rights.²⁵

The Rational Versus the Anarchic Concept of Freedom

The concept of freedom when employed rationally, presupposes the existence of reality, and with it the laws of nature, the necessity of choice among alternatives, and the fact that if one resorts to force, one must expect to be met by force. Of particular importance is the fact that it presupposes the necessity of having the voluntary cooperation of everyone who is to aid in an activity—including the owners of any property that may be involved. After taking for granted the presence of all this, the rational concept of freedom then focuses on the absence of one particular thing: the initiation of physical force—in particular, by the government.²⁶

In sharpest contrast to the rational concept of freedom is the anarchic concept. The anarchic concept of freedom evades and seeks to obliterate the fundamental and radical distinction that exists between two sorts of obstacles to the achievement of a goal or desire: "obstacles" con-

stituted by the ordinary facts of reality, including other people's voluntary choices, and obstacles constituted by the government's threat to use physical force. For example, by the nature of things, it is impossible for me to square circles, walk through walls, or be in two places at the same time. It is also not possible for me, in the actual circumstances of my life, to win the Nobel prize in chemistry or the Academy Award for best actor of the year, or to enter the automobile or steel business. There are all kinds of such things I simply cannot do. And among the things I could do, there are many I choose not to do, because I judge the consequences to myself to be highly undesirable. For example, I cannot arbitrarily decide to walk off my job in the middle of winter to take a vacation in the sun, without the very strong likelihood of being fired. I cannot drive down a city street at ninety miles an hour, nor can I strike or kill another, without running the risk of paying the penalty for violating the law. And then, there are things that are possible for me to do, and that I would very much like to do, but that would require the consent of other people, which consent they are unwilling to give. In this category, are such things as having my views published in *The New York Times* or having this book assigned in courses at leading "liberal" universities.

Absolutely none of these facts constitutes a violation of freedom, a denial of rights, or anything of the kind. In order for a violation of freedom to exist, it is not sufficient merely that someone be unable to achieve what he desires. What is necessary is that *the specific thing stopping him be the initiation of physical force*; in particular, the government's threat to use force against him in response to an action of his that does not represent the use of force.

The stock-in-trade of the anarchic concept of freedom, however, is to construe precisely such facts as a violation of freedom and rights. On the basis of the anarchic concept of freedom, it is claimed that freedom is violated any time there is anything that, for whatever reason, a person cannot do, from flying to the moon, to being able to afford a house or a college education that is beyond his reach, to committing murder.²⁷

Ironically, the anarchic concept of freedom is implicitly accepted by conservatives and fascists, as well as by anarchists and hippies. This is evident in the arguments they advance when they seek to establish the principle that it is necessary and proper to violate freedom. For example, they argue that we do not allow a man the "freedom" to murder his mother-in-law or to speed through red lights and thereby threaten the lives of others. In propounding such arguments, the conservatives and fascists casually neglect the fact that such acts constitute the initiation of force, and are so far from representing freedom that their *prohibition* is what actually constitutes freedom.

The anarchic concept of freedom, of course, is present in the assertions of Communists and socialists that their freedom of speech is violated because they are threatened with arrest for attempting to disrupt the speech of an invited speaker by shouting him down or by speaking at the same time. This assertion by the Communists and socialists neglects the fact that their action constitutes the use of someone else's property against his will—namely, the use of the meeting room against the will of the owner or lessee, who wants the invited speaker to speak, not the disrupters. It is thus the action of the Communists and socialists which is a violation of freedom in this instance—a genuine violation of the freedom of speech.

It follows from this discussion of the erroneous claims of the Communists and socialists that a prohibition on arbitrarily shouting "fire" in a crowded theater should not be construed as any kind of limitation on the freedom of speech. Arbitrarily shouting "fire" constitutes a violation of the property rights of the theater owner and of the other ticketholders, whom it prevents from using their property as they wish. When one holds the context of the rational concept of freedom, it becomes clear that it is no more a violation of freedom of speech to prohibit such speech, than it is to prohibit the speech of disruptive hecklers, or the speech of an uninvited guest who might choose to deliver a harangue in one's living room. Violations of freedom of speech occur only when the speaker has the consent of the property owners involved and then is prohibited from speaking by means of the initiation of physical force—in particular, by the government or by private individuals acting with the sanction of the government.

Because of the confusions that have been introduced into the concept of freedom, it is necessary to set matters right in a number of important concrete instances. Thus, freedom of speech is violated not when an individual does not receive an invitation to speak somewhere, but when he *does* receive it and is stopped by the government (or by private individuals acting with the sanction of the government) from accepting the invitation or exercising it. It is violated precisely by Communist and socialist disrupters whom the police refuse to remove. Ironically, in the case of a live theatrical performance, it is violated precisely when someone arbitrarily shouts "fire." Such a person violates the freedom of speech of the actors on stage.

The freedom of the press is violated and censorship exists not when a newspaper refuses to publish a story or a column that, for any reason, it regards as unworthy of publication, but when it is prepared to publish a piece and is stopped from doing so by the government. Thus, if I want to print my views in *The New York Times*, but can neither afford the advertising rates nor persuade the

publisher to give me space, my freedom of the press is not violated; I am not a victim of “censorship.” But suppose I do have the money to pay the advertising rates or could persuade the publisher to print my views, and the government disallows it—that would be a violation of the freedom of the press; that would be censorship. It is a violation of my freedom of the press if the government stops me from mimeographing leaflets, if that is all I can afford to do to spread my ideas. Again, censorship exists not when the sponsor of a television program refuses to pay for the broadcast of ideas he considers false and vicious, but when he does approve of the ideas he is asked to sponsor and yet is stopped from sponsoring them—for example, by an implicit threat of the government not to renew the license of the television station, or arbitrarily to deny him some permission he requires in some important aspect of his business.²⁸

In the same way, if I ask a woman to marry me, and she says no, my freedom is not violated. It is only violated if she says yes, and the government then stops me from marrying her—say, by virtue of a law concerning marriages among people of different races, religions, or blood types. Or, finally, if I want to travel somewhere, but lack the ability to pay the cost of doing so, my freedom of travel is in no way violated. But suppose I do have the ability to pay the cost, and want to pay it, but the government stops me—say, with a wall around my city (as existed until recently in East Berlin), a passport restriction, or a price control on oil and oil products that creates a shortage of gasoline and aviation fuel and thus stops me from driving and the airlines from flying—then my freedom of travel is violated.

What is essential in all these cases is not the fact that there is something I cannot do for one reason or another, but what it is, specifically, that stops me. Only if what stops me is the initiation of physical force—by the government in particular—is my freedom violated.

Subsequent discussions in this book will unmask the influence of the anarchic concept of freedom in the distortions that have taken place in connection with the antitrust laws—in the concepts of freedom of competition and freedom of entry, and in the related notions of private monopoly and private price control. They will also deal with the distortions to be found in the present-day notion of the “right to medical care.”²⁹

Here it must be pointed out that application of the anarchic concept of freedom operates as a cover for the violation of genuine freedom. If, for example, having to work for a capitalist, as a condition of earning wages and being able to live, is a violation of freedom and represents the existence of “wage slavery,” as the Marxists call it, then it appears that when the Communists murder the capitalists, they are merely retaliating against the aggres-

sion of capitalists—indeed, of slave owners.³⁰ Similarly, if, as the anarchic concept of freedom claims, freedom of travel or movement requires the ability to be able to afford to travel or move, then a state’s requirement of a year’s residency, say, as the condition of receiving welfare payments, can be construed as a violation of the freedom of travel or movement. Maintenance of such alleged freedom of travel or movement then requires the continued corresponding enslavement of the taxpayers, who must pay to finance it under threat of being imprisoned if they do not.

What is essential always to keep in mind is that since freedom—real freedom—is the absence of the initiation of physical force, every attempt to justify any form of restriction or limitation on freedom is actually an attempt, knowingly or unknowingly, to unleash the initiation of physical force. As such, it is an attempt to unleash the destruction of human life and property, and for this reason should be regarded as monstrously evil.

What makes the anarchic concept of freedom so destructive is the fact that in divorcing freedom from the context of rationality, it not only seeks to establish a freedom to initiate physical force, as in the cases of “wage slavery” and the anarchic concept of the freedom of travel, but also, on the basis of the consequences of such a perverted concept of freedom, provides seeming justification for the violation of freedom as a matter of rational principle. For example, the anarchic concept of freedom of speech, which claims that hecklers can speak at the same time as a lecturer and thus prevent him from communicating his thoughts, not only serves to legitimize the violation of the lecturer’s freedom of speech but also, if accepted as being a valid concept of freedom of speech, must ultimately doom the freedom of speech as a matter of rational principle. For if freedom of speech actually entailed the impossibility of communicating thought by speech, because hecklers could continually interrupt the speaker, respect for rationality—for the value of communicating thought—would then require the denial of the freedom of speech.

Such a vicious absurdity arises only on the basis of the anarchic concept of freedom. It does not arise on the basis of the rational concept of freedom. Freedom of speech rationally means that the lecturer or invited speaker has the right to speak and that hecklers and disrupters are violating the freedom of speech. The rational concept of freedom establishes freedom of speech precisely as the *safeguard of the communication of thought*, not its enemy. It is vital to keep this principle in mind today in an environment in which many university campuses have been transformed into virtual zoos, in which cowardly and ignorant administrators regularly tolerate disruptions of speech by gangs of delinquents masquerading as

students. Such university administrators thereby abandon their responsibility to maintain their universities as the centers of teaching and learning that in their nature they are supposed to be. In tolerating anarchic violations of freedom of speech in the name of freedom of speech, they pave the way for the outright fascistic destruction of freedom of speech in the name of rationality.

The Decline of Freedom in the United States

In the twentieth century, freedom in the United States has been in decline. A twofold measure of this decline is the fact that, with little if any exaggeration, it is now the case that the average mugger has less to fear from the police and courts than the average successful businessman or professional has to fear from the Internal Revenue Service. In allowing common crime to go increasingly unchecked, the government has increasingly failed in its function of securing the individual's freedom in relation to other private individuals. At the same time, as the limits on its powers have been removed, it has itself increasingly violated the freedom of the individual. The government's energies and efforts have more and more been diverted from the protection of the individual's freedom to the violation of it.

To some extent, the process of the destruction of freedom has taken place under the code words of combatting "white-collar crime" instead of "blue-collar crime." The latter type of crime is genuine crime, entailing the initiation of physical force. The former type of crime incorporates some elements of genuine crime, such as fraud and embezzlement, but consists mainly of fictitious crimes—that is, perfectly proper activities of businessmen and capitalists which are viewed as crimes from the perverted perspective of Marxism and other varieties of socialism, such as charging prices that are allegedly "too high" or paying wages that are allegedly "too low."

A profreedom political party would have as the essence of its platform the replacement of the government's suppression of the activities of businessmen and other peaceful private individuals with the rightful suppression of the activities of common criminals, such as muggers, robbers, and murderers. Its essential goal would be the total redirection of the energies of the government away from interference with the peaceful, productive activities of the citizens to forcibly and effectively combatting the destructive activities of common criminals.

The extent to which this can happen, and thus the future of freedom in the United States, depends first of all on the concept of freedom being properly understood, and then on its being upheld without compromise in every instance in which freedom is violated or threatened, from the police turning their backs on campus disruptions and even open rioting and looting in major

cities, to income tax audits and the ever growing array of government regulations.

All of the major problems now being experienced in the United States have as an essential element the inconsistent application or outright abandonment of the country's own magnificent original principle of a government upholding individual freedom. Every violation of that principle—every act of government intervention into the economic system—represents the use of physical force either to prevent individuals from acting for their self-interest or to compel them to act against their self-interest. It is no wonder that as the violations of freedom multiply, people are less and less able to serve their self-interests and thus suffer more and more. In order for the American people once again to succeed and prosper, it is essential for the United States to return to its founding principle of individual freedom.

The Growth of Corruption as the Result of the Decline of Freedom

Closely and necessarily accompanying the destruction of freedom in the United States has been the growing corruption both of government officials and of businessmen, who are increasingly under the power of the officials. The ability to violate the freedom of businessmen gives to the government officials the power to deprive businessmen of opportunities to earn wealth or to retain wealth they have already earned. The power of the officials is fundamentally discretionary, that is, it may or may not be used, as they decide. This is always the case with legislators contemplating the enactment of new laws. It is often the case with officials charged with the execution of a law—if they have the power to decide whether or not to enact this or that new regulation in the course of its execution, and whether or not to apply the regulation in any given case, or to what extent.

This situation inevitably creates an incentive on the part of businessmen to bribe the officials, in order to avoid the passage of such laws or the enactment or application of such regulations and thus to go on with the earning of wealth or to keep the wealth they have already earned. It is a situation in which businessmen are made to pay the officials for permissions to act when properly they should be able to act by right—by the right to the pursuit of happiness, which includes the right to the pursuit of profit.

At the same time, the government's ability to violate freedom gives it the power to provide businessmen with subsidies and to damage their competitors. This creates corruption of a much worse character, one in which businessmen are led to offer bribes not to defend what is theirs by right, but as part of an act of depriving others of what belongs to those others by right. Few business-

men are moral philosophers, and those who may have begun their practice of bribing government officials in order simply to avoid harm to themselves cannot be counted upon always to keep in mind the distinction between an act of self-defense and an act of aggression, especially when they must operate increasingly in the conditions of a virtual jungle, in which competitors are prepared to use the government against them and in which large and growing numbers of other businessmen are all too willing to gain subsidies at their expense. The result is a powerful tendency toward the destruction of the whole moral fabric of business.

The obvious solution for this problem of corruption is, of course, the restoration of the businessman's freedom and his security from the destructive actions of the government officials. When the businessman can once again act for his profit by right rather than permission, when the government has lost the power both to harm him and to harm others for his benefit, the problem of such bribery and corruption will shrivel to insignificance.³¹

3. Capitalism and the Origin of Economic Institutions

To the degree that they exist, freedom and the pursuit of material self-interest, operating in a rational cultural environment, are the foundation of all the other institutions of capitalism. And the study of these institutions and their functioning is the substance of the science of economics.

If individuals both possess freedom and, at the same time, rationally desire to improve their lives and well-being, then they have only to use their minds to look at reality, consider the various opportunities that nature and the existence of other people offer them for serving their self-interest, and choose to pursue whichever of the opportunities confronting them they judge best. They can do whatever they judge is most in their self-interest to do, provided only that they do not initiate the use of force against others.

What people do in these circumstances is spontaneously to set about establishing, or extending and reinforcing, all the other institutions, in addition to freedom and limited government, that constitute a capitalist economic system, such as private ownership of the means of production, saving and capital accumulation, exchange and money, division of labor, and the price system.

Thus, in pursuing their rational self-interest under freedom, they appropriate previously unowned land and natural resources from nature and make them into private property and thus privately owned means of production. Private property in products, including capital goods, then follows on the basis of private property in land and natural resources: the owners of land and natural re-

sources own the products that result from them, including those which they use as means of further production. In addition, of course, they can exchange their products with others for services. These others then also own products, including capital goods, and can, of course, obtain land and natural resources from their original owners by means of purchase or, in primitive conditions, barter exchange.

Being secure in their possession of property from violent appropriation by others, and rational enough to act on the basis of long-run considerations, individuals save and accumulate capital, which increases their ability to produce and consume in the future (for example, following the appropriation of land, they clear trees, remove rocks, drain, irrigate, build, and do whatever else is necessary to establish and improve farms and mines and, later on, commercial and industrial enterprises).

They also perceive the advantages of establishing division of labor and performing exchanges with others. They perceive that some individuals are more efficient than others in the production of certain goods, whether by reason of personal ability or because of the circumstances of the territory in which they live, and that an advantage is to be gained by individuals concentrating on their areas of greater efficiency and exchanging the results.³²

They perceive the advantages of indirect exchange—that is, of accepting goods not because they want them themselves, but because others want them and the goods can thus be used as means of further exchanges. Out of indirect exchange money develops, with the result that the division of labor is enabled radically to intensify—to the point where each individual finds it to his interest to produce or help to produce just one or at most a very few things, for which he is paid money, which he in turn uses to buy from others virtually all that he himself consumes.³³

In the context of a division-of-labor, monetary economy, the individual's pursuit of his material self-interest gives rise to the narrower principle of financial self-interest—that is, of preferring, other things being equal, to buy at lower prices rather than higher prices and to sell at higher prices rather than lower prices. These are the ways to increase the goods one can obtain by the earning and spending of money. In combination they represent the profit motive—the principle of “buying cheap and selling dear.”

The individual's pursuit of self-interest also gives rise to economic inequality, as those who are more intelligent and ambitious outstrip those who are less intelligent and ambitious; and to economic competition, as different sellers seek to sell to the same customers, and as different buyers seek to buy one and the same supply of a good or service.

The combination of the profit motive and the freedom

of competition, in turn, constitutes the basis of the price system and all of its laws of price determination.

Thus, rational self-interest and the individual's freedom to act on the basis of it underlie private property and private ownership of the means of production, saving and capital accumulation, the division of labor, exchange and money, financial self-interest and the profit motive, economic inequality, economic competition, and the price system—in a word, the whole range of capitalism's economic institutions.

The combined effect of these institutions is *economic progress*—that is, the increase in the productive power of human labor and the consequent enjoyment of rising standards of living. Economic progress is the natural accompaniment of rationality and the freedom to act on it. This is so because the continued exercise of rationality creates a growing sum of scientific and technological knowledge from generation to generation. This, together with the profit motive, the freedom of competition, the incentive to save and accumulate capital, and the existence of a division-of-labor society, is the essential basis of continuous economic progress.³⁴

Economic progress is the leading manifestation of yet another major institutional feature of capitalism: *the harmony of the rational self-interests of all men*, in which the success of each promotes the well-being of all. The basis of capitalism's harmony of interests is the combination of freedom and rational self-interest operating in the context of the division of labor, which is itself their institutional creation. Under freedom, no one may use force to obtain the cooperation of others. He must obtain their cooperation voluntarily. To do this, he must show them how cooperation with him is to their self-interest as well as his own, and, indeed, is *more* to their self-interest than pursuing any of the other alternatives that are open to them. To find customers or workers and suppliers, he must show how dealing with him benefits them as well as him, and benefits them more than buying from others or selling to others. As will be shown, the gains from the division of labor make the existence of situations of mutual benefit omnipresent under capitalism.³⁵ The division of labor, in combination with the rest of capitalism, represents a regular, institutionalized arrangement whereby the mind of each in serving its individual possessor, serves the well-being of a multitude of others, and is motivated and enabled to serve their well-being better and better.

In sum, capitalism, with its economic progress and prosperity, is the economic system of a free society. It is the economic system people achieve if they have freedom and are rational enough to use it to benefit themselves. As I have said, it represents a self-expanded power of human reason to serve human life.³⁶

4. Capitalism and the Economic History of the United States

The development of all the institutional features of capitalism is well illustrated by the economic history of the United States. Of course, the United States was by no means the perfect model of a capitalist country. Negro slavery existed, which denied all freedom to blacks and prevented them from pursuing their material self-interests. This was in total contradiction of the principles of capitalism. And other important contradictions existed as well, such as a policy of protective tariffs, public canal and turnpike building, the government's claim to ownership of the western lands and its consequent ability to use land grants to subsidize uneconomic railroad building, and, very important, the government's promotion of the use of debt as backing for paper money, which repeatedly resulted in financial panics and depressions when substantial debtors failed, as, in the nature of the case, they had to.³⁷

Nevertheless, the history of the United States shows a government committed in principle to upholding the freedom of the individual and, for the white population, doing so in fact to a degree never achieved before or since. And thus, following the establishment of the United States, we observe a century-long process of the appropriation of land and establishment of private property and private ownership of the means of production, as people were made free to appropriate previously ownerless territory and moved west to do so. This period represents the most important historical example of the process of establishing private property and private ownership of the means of production described in the preceding section. By and large, the settlers simply moved into what was virtually an empty continent and made major portions of it into private property by direct appropriation from nature. The private property that exists today in the United States can generally be traced back, through intervening purchases and sales, to such original appropriations from nature.³⁸

The history of the United States was also characterized by the rapid development of the division of labor and the growth of a monetary economy. The largely self-sufficient pioneers of colonial times were succeeded by farmers producing more and more for the market and buying goods in the market, including all manner of equipment and other aids that greatly increased their ability to produce. The result of the rising productivity of labor in agriculture was a steady shift in population away from farming and toward towns and cities, which sprang up in the wilderness and grew rapidly as centers of an ever more prosperous commerce and industry.

The growing concentration of farmers on producing

for the market and the movement of more and more of their sons and daughters to the towns and cities to find employment constituted the actual building of a division-of-labor society. This was a process that was dictated by considerations of self-interest on the part of millions of individual people. Each individual farmer who devoted his labor to producing crops for the market did so because he judged that he would be better off with the products he could buy with the money he earned than he would be with the products he could produce for himself with the same labor. Each individual son or daughter of a farmer who moved to a town or city to find employment did so because he judged that he would be better off by doing so—that the income to be earned in a town or city exceeded the income to be made as a farmer and any allowance for the self-produced goods and other benefits associated with living on a farm. Thus, the self-interested actions of millions of individuals is what created a division-of-labor society in the United States and everywhere else that it exists.

The security of property made the American people both industrious and provident, because they knew that they could keep all that they earned and be able to benefit from all that they saved. (There was no income tax prior to 1913.) Not surprisingly, they were considered to be the hardest-working people in the world. And their consequent high rate of saving ensured that each year a substantial proportion of their production took the form of new and additional capital goods, which had the effect of increasing their ability to produce and consume in succeeding years.

The freedom of production in the United States led to an unprecedented outpouring of innovations—to the steady introduction of new and previously unheard of products and to the constant improvement of methods of production. This, along with the constant availability of an adequate supply of savings to implement the advances, produced the most rapid and sustained rate of economic progress in the history of the world.³⁹

In the process, some individuals achieved enormous personal wealth and distinction. But their success was not the cause of anyone else's impoverishment. It was, on the contrary, precisely the means whereby the general standard of living was raised and all were progressively enriched. For these individuals made the innovations and built the industries that were the source of the growing volume of goods enjoyed by all.

And, overall, guiding the entire process of production in the American economy were the profit motive and the price system. The "dollar-chasing Americans," as they were called, were vitally concerned with earning money. Calculations of profit and loss governed every business decision and, therefore, practically every decision con-

cerning the production of goods and services. Because of the freedom of competition, those business firms succeeded which found ways to reduce their costs of production and offer better goods at lower prices—earning high profits by virtue of low costs and large volume.

The economic history of the United States can be understood on the basis of a single fundamental principle: *people were free and they used their freedom to benefit themselves*. Each individual was free to benefit himself, and the necessity of respecting the freedom of others necessitated that he benefit them as well if he was to have them as workers, suppliers, or customers. Because people had the freedom and the desire to benefit themselves, they went ahead and virtually all of them actually succeeded in benefitting themselves.

In 1776 the present territory of the United States was an almost empty continent, whose cities either did not exist or were little more than coastal villages. Its population consisted of approximately half a million Indians, who lived on the edge of starvation, and three million settlers, most of whom were semi-self-sufficient farmers living in extreme poverty. In less than two centuries, it was transformed into a continent containing the two hundred million richest people in the history of the world; a continent crisscrossed with highways, railways, telephone and telegraph lines; a continent filled with prosperous farms and dotted with innumerable towns and cities that were the sites of factories using methods of production and producing all manner of goods that probably could not even have been imagined in 1776.

One should ask how the United States' economy got from where it was then to where it is even now. One should ask how Pittsburgh, Cleveland, Detroit, Chicago, St. Louis, San Francisco, Los Angeles, Houston, and Dallas came to be the great cities they all were, not very long ago, and, for the most part, still are. One should ask how New York City grew from a population of twenty thousand to eight million, and how Boston and Philadelphia could increase in size thirty-five and one hundred times over. One should ask where all the means of transportation and communication, all the farms and factories, houses and stores, and all the incredible goods that fill them came from.

The answer, as I say, is astoundingly simple. What was achieved in the United States *was the cumulative, aggregate result of tens of millions of people, generation after generation, each pursuing his individual self-interest*—in the process, necessarily helping others to achieve their self-interests. And what made this possible was individual freedom.

Thus, eastern farmers realized that the land in the Midwest and West was better for many purposes than the land in the East, and that a higher income was to be made

by moving there. And so they moved. Merchants realized that these farmers needed supplies and that money was to be made in supplying them. And so they opened clusters of stores and built their houses at supply points in proximity to the farmers, thus laying the base of towns and cities. They made money and expanded their operations. Others perceived the growing trade and the money to be made in improving transportation to the new regions. They built barge lines and stagecoach lines, then steamship companies and railroads, and made money.

Businessmen and inventors, often one and the same, were constantly on the lookout for the new and the better. They discovered and introduced thousands upon thousands of improvements both in products and in methods of production, with each new advance serving as the base for something still newer and still better. These businessmen and inventors built the factories and the industries that made the cities and towns. The rest of the population, always on the lookout for better jobs, recognized the advantages of employment in the new industries and the new cities and so took the ever improving, ever better-paying jobs they offered.

All this happened because it was to the rational self-interest of individuals to make it happen and because no one could use force to stop them from making it happen. The British had tried to prevent the development of the territory west of the Appalachian Mountains—to set it aside as a kind of gigantic wildlife preserve, so to speak—but the American Revolution overthrew their rule and cleared the way for the unprecedented economic progress I have described.

The rising prosperity of each generation brought about a continual doubling and redoubling of the population, as a higher and higher proportion of children survived to adulthood, and as an ever growing flood of immigrants bought, borrowed, and sometimes stole their way to the shores of what—in their awe and admiration for the United States and its freedom—they called “God’s country.”

In recent years, it is true, the economic glow of the United States has lost much of its luster. While advances continue in some fields, such as computerization, major areas of economic life, and the economic conditions confronting large numbers of people, have clearly fallen into a state of decline. Major industries, such as automobiles and steel, and entire industrial regions—the Northeast and the Midwest, once the backbone of the American economy—are in decline. What was once the industrial heartland of the United States is now known as the *rust belt*—a dreadful, but accurate description of its condition. Detroit, once the home of the American automobile industry and the leading industrial city in the world is now on the verge of losing its last automobile factory,

and growing portions of it are becoming uninhabited. The housing stock, industry, and downtown shopping districts of many other large cities are also in a state of profound decay. For some years, homeownership has been beyond the reach of most people, and a sharp rise in the price of electricity, heating oil, and gasoline has made the operation of homes and automobiles far more costly and has undercut people’s ability to afford other goods. The supply of power plants is becoming inadequate. A growing number of bridges, highways, and commercial aircraft are in need of major overhaul or replacement. Large-scale unemployment persists.

This book makes clear that the cause of such problems is the progressive abandonment of capitalism and the undermining of its institutions over a period of several generations. This is a process that has finally assumed dimensions so great as to jeopardize the continued functioning of the economic system.

There has been a steady increase in government spending for alleged social welfare, which has been financed by a system of progressive income and inheritance taxation and by budget deficits and inflation of the money supply. These policies, in turn, destroy incentives to produce and the ability to save and accumulate capital. They have been coupled with a steadily increasing burden of government regulations restricting or prohibiting economically necessary activities and encouraging or compelling unnecessary, wasteful, and even absurd activities. For example, the production of fuel has been restricted or even prohibited by price controls and so-called environmental legislation, while the hiring and promotion of unqualified employees has been encouraged and even compelled under systems of government imposed racial and sexual quotas.

The consequence of all of this has been growing economic stagnation, if not outright economic decline, a situation punctuated by rapidly rising prices, growing unemployment, and sporadic shortages.

In recent years, it appears that there has been some recognition of the nature of our problems. Unfortunately, the recognition does not yet go deep enough nor is it yet nearly widespread enough. Thus its benefits are likely to prove elusive or at least extremely short-lived. For example, a major undermining of the OPEC cartel and partial retracement of the price of oil took place in the 1980s, mainly as a result of the repeal of price controls on oil and the easing of “environmental” regulations early in the decade. But now this improvement is in the process of being reversed, through the reimposition and further extension of “environmental” regulations. At the same time, other forms of government interference and government spending continue to grow, and federal budget deficits continue at an alarming level, which makes

it likely that the government will turn either to destructive tax increases or to a no less destructive acceleration of inflation. Even the sudden collapse of socialism in Eastern Europe and the former Soviet Union provide little cause for long-term optimism about the economic system of the United States. This is because, as will be explained later, all the essentials of socialism live on in the ecology movement, and are enjoying growing influence in the United States even while socialism in the form of Marxism is in decline in most of the world.⁴⁰

5. Why Economics and Capitalism Are Controversial

In propounding sound economic theory and thus in presenting the case for capitalism, this book cannot avoid being highly controversial. It is necessary to explain the reasons.

The Assault on Economic Activity and Capitalism

Virtually every aspect of capitalism and thus of economic activity is savagely denounced by large segments of public opinion. The pursuit of self-interest is condemned as evil, and of material self-interest as “vulgar” besides. Freedom under capitalism is ridiculed as “the freedom to starve” and as “wage slavery.” Private property is condemned as theft—from a patrimony allegedly given by God or Nature to the human race as a whole. Money is denounced as the “root of all evil”; and the division of labor, as the cause of one-sided development, narrowness, and “alienation.”

The profit motive is attacked as the cause of starvation wages, exhausting hours, sweatshops, and child labor; and of monopolies, inflation, depressions, wars, imperialism, and racism. It is also blamed for poisoned foods, dangerous drugs and automobiles, unsafe buildings and work places, “planned obsolescence,” pornography, prostitution, alcoholism, narcotics abuse, and crime. Saving is condemned as hoarding; competition, as “the law of the jungle”; and economic inequality, as the basis of “class warfare.” The price system and the harmony of interests are almost completely unheard of, while economic progress is held to be a “ravaging of the planet,” and, in the form of improvements in efficiency, a cause of unemployment and depressions. At the same time, by the same logic, wars and destruction are regarded as necessary to prevent unemployment under capitalism.

Virtually all economic activity beyond that of manual labor employed in the direct production of goods is widely perceived as parasitical. Thus businessmen and capitalists are denounced as recipients of “unearned income,” and as “exploiters.” The stock and commodity markets are denounced as “gambling casinos”; retailers and wholesalers, as “middlemen,” having no function

but that of adding “markups” to the prices charged by farmers and manufacturers; and advertisers, as inherently guilty of fraud—the fraud of attempting to induce people to desire the goods that capitalism showers on them, but that they allegedly have no natural or legitimate basis for desiring.

Despite the obvious self-contradictions, capitalism is simultaneously denounced for impoverishing the masses and for providing them with “affluence,” for being a rigid class society and for being dominated by the upstart nouveau riche, for its competition and for its lack of competition, for its militarism and for its pacifism, for its atheism and for its support of religion, for its oppression of women and for its destruction of the family by making women financially independent.

Overall, capitalism is denounced as “an anarchy of production,” a chaos ruled by “exploiters,” “robber barons,” and “profiteers,” who “coldly,” “calculatingly,” “heartlessly,” and “greedily” consume the efforts and destroy the lives of the broad masses of average, innocent people.

On the basis of all these mistaken beliefs, people turn to the government: for “social justice”; for protection and aid, in the form of labor and social legislation; for reason and order, in the form of government “planning.” They demand and for the most part have long ago obtained: progressive income and inheritance taxation; minimum-wage and maximum-hours laws; laws giving special privileges and immunities to labor unions; antitrust legislation; social security legislation; public education; public housing; socialized medicine; nationalized or municipalized post offices, utilities, railroads, subways, and bus lines; subsidies for farmers, shippers, manufacturers, borrowers, lenders, the unemployed, students, tenants, and the needy and allegedly needy of every description. They have demanded and obtained food and drug regulations, building codes and zoning laws, occupational health and safety legislation, and more. They have demanded and obtained the creation of additional money, and the abolition of every vestige of the gold standard—to make possible the inflation of the money supply without limit. They have demanded this last in the belief that the additional spending the additional money makes possible is the means of maintaining or achieving full employment, and in the belief that creating money is a means of creating capital for lending and thus of reducing interest rates. The ability to create money has also been demanded because it is vital in enabling additional government expenditures to be financed by means of budget deficits and thus in fostering the delusion that the government can provide benefits for which the citizens do not pay. And when, as is inevitable, the policy of inflation results in rising prices, capital decumulation, and the

destruction of credit, people demand price and wage controls, and then, in response to the shortages and chaos that result, the government's total control over the economic system, in the form of rationing and allocations.

In the face of such ideas and demands, which have swept over the country with the force of a great flood, traditional American values of individual rights and limited government have appeared trivial and antiquated—appropriate perhaps to an age of independent farmers, but by no means to be permitted to stand in the way of what a frightened and angry mass of people perceive as the requirements virtually of their self-preservation. Indeed, so complete has been the destruction of traditional American values, that the concept of individual rights has itself been made over into a vehicle serving demands for government subsidies and extensions of government power—in such forms as the assertion of “rights” to jobs, housing, education, pensions, medical care, and so on.

This book flies in the face of all such anticapitalistic ideas and demands. Its thesis implies that never have so many people been so ignorant and confused about a subject so important, as most people now are about economics and capitalism. It shows that in its logically consistent form of *laissez-faire* capitalism—that is, with the powers of government limited to those of national defense and the administration of justice—capitalism is a system of economic progress and prosperity for all, and is a precondition of world peace.

The Prevailing Prescientific Worldview in the Realm of Economics

There are a number of mutually reinforcing reasons for the prevailing mass of errors about economics and capitalism.

First, even though this is the late twentieth century, it is no exaggeration to say that in the realm of economics, the thought of most people continues to bear the essential characteristics of the mentality of the Dark Ages or of primitive peoples in general. What I mean by this is that prior to the development of a scientific worldview in the Renaissance, it was common for people even in Western Europe to interpret natural phenomena as the result of the operation of good or evil spirits. Thus, if a flood came and washed away their huts, or if their animals died of disease, polytheistic primitive peoples would think the explanation lay in the anger of a river god or some other deity. Similarly, the supposedly monotheistic Europeans of the Dark Ages would believe the explanation lay in the curse of some witch or other evil spirit. Both believed that their protection from such harm lay in securing the aid of a more powerful benevolent spirit, whether another deity or an angel, or simply the one and only deity. What was essential was that they believed that their harm

resulted from the exercise of arbitrary power by evil forces and that their security depended on obtaining the aid of a greater, stronger arbitrary power who would act on their behalf.

As the preceding discussion of the assault on economic activity and capitalism should make clear, this is precisely the worldview people continue to apply in the present day in the realm of economics. Again and again they view their economic harm as caused by the ill will of an arbitrary power—above all, “big business.” And they believe that their protection depends on the good will of a bigger, tougher, stronger arbitrary power—namely, the government—which will act on their behalf. If, for example, the level of wages or prices or the quantity or quality of housing, medical care, education, or anything else is not to people's satisfaction, the explanation, they believe, is that evil businessmen are responsible. The solution, they believe, is for the government, which is more powerful than the businessmen, to use its greater power on behalf of the people.⁴¹

In contrast, the view of the economic world imparted by economic science is as far removed from that of the primitive mentality as is the view of the physical world that is imparted by the sciences of physics and chemistry. The worldview imparted by economics is, like that of physics and chemistry, one of operation according to natural laws which can be grasped by human intelligence. The domain of the natural laws of economics is, of course, that of the rationally self-interested actions of individuals insofar as they take place under freedom and center on the production of wealth under a division of labor.

This scientific view of economic phenomena, even though in existence since the late eighteenth century in the writings of the Physiocrats and the early British classical economists, has been prevented from replacing the primitive worldview. It has been prevented by the combined operation of the factors explained in the remainder of this section.

Economics Versus Unscientific Personal Observations

Everyone is a participant in economic activity and as such develops or accepts opinions about economic life that seem consistent with his own observations of it. Yet those opinions are often mistaken, because they rest on too narrow a range of experience, which renders them inconsistent with other aspects of experience of the same subject. Examples of this phenomenon in the everyday world of physical reality are such naive beliefs as that sticks bend in water, that the earth is flat, and that the sun revolves around the earth. In contrast with such naïveté, a scientific process of thought seeks to develop the theory of a subject based on logical consistency with *all* the

valid observations pertaining to it. Thus, the visual appearance of sticks being bent in water is reconciled with the fact that they continue to feel straight when subjected to touch; the reconciliation being by knowledge of the refraction of light caused by water. The earth's appearance of flatness is reconciled with such observations as the masts of ships first becoming visible on the horizon by knowledge of the very gradual curvature of the earth. The appearance of the sun's revolution about the earth is reconciled with knowledge of the sun's relationship to other observable heavenly bodies through knowledge of the earth's rotation about its axis.

Economics suffers from an apparent conflict between personal observation and scientific truth probably to a greater extent than most other sciences. This is because of the very nature of the system of division of labor and monetary exchange. Every participant in the economic system is a specialist, aware of the effect of things on his own specialization. As a rule, he does not stop to consider their effect on other specializations as well; nor, as a rule, does he consider what their longer-run effect on him might be were he to change his specialization. As a result of this, people have come to believe such things as that improvements in production, which can in fact necessitate the shrinkage or total disappearance of employment in any particular branch of the division of labor, are economically harmful. By the same token, they have come to believe that acts of destruction, which can in fact result in an expansion of employment in particular branches of the division of labor, are economically beneficial.⁴²

Closely related to the failure to look beyond one's own current specialization is the widespread confusion between money and wealth. In a division-of-labor economy everyone is naturally interested in earning money and comes to measure his economic well-being by the amount of money he earns. Thus, it is extremely easy for people to conclude that anything that enables the average person to earn more money is desirable, while anything that results in the average person's earning less money is undesirable. It takes a scientific analysis to show that while each individual is always economically best off earning as much money as *the freedom of competition allows him to earn*, people are not economically better off when average earnings increase as the result of government policies of creating money, or because the government violates the freedom of competition. Indeed, economics shows that lower monetary earnings without money creation and without violations of the freedom of competition represent a higher actual standard of living than do higher monetary earnings with them.⁴³ Along these lines, there are important cases in which, even in the absence of money creation, it turns out that a lower "national income" or "gross national product" signifies

a more rapid rate of increase in the production of wealth and improvement in human well-being than does a higher "national income" or "gross national product."⁴⁴

Economics Versus Altruism

If economics merely contradicted people's unscientific conclusions based on their personal observations, its path would be difficult enough. Its problems are enormously compounded, however, by the fact that its teachings also contradict some of the most deeply cherished moral and ethical doctrines, above all, the doctrine that the pursuit of self-interest by the individual is harmful to the interests of others and thus that it is the individual's obligation to practice altruism and self-sacrifice.

Economics as a science studies the rational pursuit of material self-interest, to which it traces the existence of all vital economic institutions and thus of material civilization itself, and from which it derives an entire body of economic laws. It cannot help concluding that rational self-interest and the profit motive are profoundly benevolent forces, serving human life and well-being in every respect, and that they should be given perfect freedom in which to operate. Nevertheless, traditional morality regards self-interest as amoral at best, and, indeed, as positively immoral. It considers love of others and self-sacrifice for the sake of others to be man's highest virtues, around which he should build his life.

Thus, the teachings of economics are widely perceived as a threat to morality. And, by the same token, the anticapitalistic slogans described earlier in this section are perceived as expressions of justified moral outrage. As a result, economics must make its way not merely against ignorance, but against ignorance supported by moral fervor and self-righteousness. Without the issue being named, economists are in a similar position to the old astronomers, whose knowledge that the earth revolved about the sun not only appeared to contradict what everyone could see for himself but also stood as a challenge to the entire theological view of the universe. Economics and capitalism are a comparable challenge to the morality of altruism.

It is almost certain that economics and capitalism will be unable to gain sufficient cultural acceptance to ensure the influence of the one and the survival of the other until there is a radical change in people's ideas concerning morality and ethics, and that this change will have to be effected in fields other than economics—notably, philosophy and psychology. But even so, economics itself has an enormous contribution to make in changing people's ideas on these subjects, which every advocate of rational self-interest would be well advised to utilize.

A major reason for the condemnation of self-interest

is, certainly, beliefs about its economic consequences. If people did not believe, for example, that one man's gain is another's loss, but, on the contrary, that in a capitalist society one man's gain is actually other men's gain, their fear and hatred of self-interest could probably not be maintained. Yet precisely this is what economics proves. It proves what is actually the simplest thing in the world. Namely, that if individuals rationally seek to do good for themselves, *each* of them can in fact *achieve* his good. It proves that in a division-of-labor, capitalist society, in the very nature of the process, in seeking his own good, the individual promotes the good of others, whose self-interested actions likewise promote the achievement of his good. Economics proves the existence of a harmony of the rational self-interests of all participants in the economic system—a harmony which permeates the institutions of private ownership of the means of production, economic inequality, and economic competition. At the same time, it shows that the fear of self-interest and the consequent prohibition of its pursuit is the one great cause of paralysis and stagnation—that if individuals are prohibited from doing good for themselves, their good simply cannot be achieved.

Economics Versus Irrational Self-Interest

The teachings of economics encounter opposition not only from the supporters of altruism, but also from the practitioners of an irrational, short-sighted, self-defeating form of self-interest, as well. These are, above all, the businessmen and wage earners whose short-run interests would be harmed by the free competition of capitalism and are protected or positively promoted by policies of government intervention, and who do not scruple to seek government intervention. For example, the businessmen and wage earners who seek government subsidies, price supports, tariffs, licensing laws, exclusive government franchises, labor-union privileges, immigration quotas, and the like.

Such businessmen and wage earners form themselves into pressure groups and lobbies, and seek to profit at the expense of the rest of the public. They and their spokesmen unscrupulously exploit the economic ignorance of the majority of people by appealing to popular misconceptions and using them in support of destructive policies. Their action is self-defeating in that the success of each group in achieving the privileges it wants imposes losses on other groups that are greater than its gains; at the same time, its gains are canceled by the success of other groups in obtaining the special privileges they want. The net effect is losses for virtually everyone. For not only does each group plunder others and in turn is plundered by them, but, in the process, the overall total of what is produced is more and more diminished, as well.

For example, what farmers gain in subsidies they lose in tariffs, higher prices because of monopoly labor unions, higher taxes for welfare-type spending, and so on. Indeed, the gains of each type of farmer are even canceled in part by the gains of other types of farmers—for example, the gains of wheat farmers are lost in part in paying higher prices for other subsidized farm products, like cotton, tobacco, milk, and butter. In the same way, the benefit of the higher wages secured by a labor union is lost in the payment of higher prices for products produced by the members of all other unions, as well as in the payment of higher prices caused by subsidies, tariffs, and so on. The net effect works out to be that less of virtually everything is produced, because such policies both reduce the efficiency of production and prevent people from being employed. Virtually everyone is made worse off—those who become unemployed and those who continue to work. Because of the inefficiencies introduced, the latter must pay prices that are increased to a greater degree than their incomes, and they must also use part of their incomes to support the unemployed.

The pressure-group members may subjectively believe that they are pursuing their self-interests. The supporters of altruism and socialism may believe that the absurd process of mutual plunder carried on by such groups represents capitalism and the profit motive. But the fact is that self-interest is not achieved by pressure-group warfare. Nor is the activity of pressure groups a characteristic of capitalism. On the contrary, it is the product of the “mixed economy”—an economy which remains capitalistic in its basic structure, but in which the government stands ready to intervene by bestowing favors on some groups and imposing penalties on others.

(As used in this book, the term “mixed economy” is to be understood as what von Mises called a “hampered market economy.” As he explains, an economic system is either a market economy, in which case its operations are determined by the initiative of private individuals motivated to make profits and avoid losses, or a socialist economy, in which case its operations are determined by the government. These two alternatives cannot be combined into an economy that would somehow be a mixture of mutually exclusive possibilities. Thus, the term “mixed economy” is to be understood in this book as denoting a hampered market economy.⁴⁵)

In contrast, under genuine capitalism—laissez-faire capitalism—the government has no favors to give and no arbitrary penalties to impose. It thus has nothing to offer pressure groups and creates no basis for pressure groups being formed out of considerations of self-defense.

The absurdity of the pressure-group mentality manifests itself in the further fact that it provides powerful support for the fear and hatred of self-interest emanating

from altruism, and thus leads to the suppression of the pursuit of self-interest. The practitioners of pressure-group warfare are in the contradictory position of wanting to serve their own particular interests and yet, with good reason, simultaneously having to fear and oppose the pursuit of self-interest by others, since under pressure-group warfare, one man's gain actually is another's loss. The result is that while people strive to achieve their self-interest in their capacity as members of pressure groups, yet, in their capacity as citizens, they strive to create social conditions in which the pursuit of self-interest of any kind becomes more and more impossible. Because, given their mentality, they cannot help but regard the pursuit of self-interest as antisocial and thus must oppose it for everyone else.

In these ways, the irrational pursuit of self-interest represented by pressure group warfare actually represents people actively and powerfully working against their self-interest.

The practitioners of pressure group-warfare condemn economics because they do not understand it—indeed, may have made themselves incapable of understanding it. Their mental horizon is so narrow and confined that it does not extend beyond what promotes or impairs their immediate self-interest in their present investments and lines of work. They perceive the doctrines of economics entirely from that perspective. Thus, a shoe manufacturer of this type, who could not withstand foreign competition, hears economics' doctrine of free trade from no other perspective than that, if implemented, it would put him out of the shoe business. And thus he concludes that he has a self-interest in opposing the doctrine of free trade. And, for similar reasons, virtually every other doctrine of economics is opposed by the pressure groups concerned. To use the analogy to astronomy once more, it is as though people mistakenly concluded not only that the sun circled the earth and that morality itself supported the proposition, but also that their personal well-being required them to oppose any alternative explanation.

Economics Versus Irrationalism

The preceding discussion points to the most fundamental and serious difficulty economics encounters, which is a growing antipathy to reason and logic as such. Economics presupposes a willingness of the individual to open his mind to a view of the entire economic system extending over a long period of time, and to follow chains of deductive reasoning explaining the effects of things on all individuals and groups within the system, both in the long run and in the short run.⁴⁶ This broadness of outlook that economics presupposes is, unfortunately,

not often to be found in today's society. Under the influence of irrationalist philosophy, people doubt their ability to achieve understanding of fundamental and broad significance. They are unwilling to pursue matters to first causes and to rely on logic to explain effects not immediately evident.

In large part, people's reluctance to think has been the result of a two-centuries-long attack on the reliability of human reason by a series of philosophers from Immanuel Kant to Bertrand Russell—an attack which began soon after the birth of economic science. More than any other factor, this attack on the reliability of reason has been responsible for the perpetuation of the mentality of primitive man in the realm of economics.⁴⁷

A leading consequence and manifestation of this attack has been the appearance of a series of irrationalist writers, who have come to the fore in field after field, and who have taken a positive delight in establishing the appearance of paradox and in seeming to overturn all that reason and logic had previously been thought to prove true beyond doubt. The most prominent figure of this type in economics is Keynes, who held that "Pyramid-building, earthquakes, even wars may serve to increase wealth, if the education of our statesmen on the principles of the classical economics stands in the way of anything better."⁴⁸ In other fields, renowned authorities proclaim that parallel lines meet, that electrons can cross from one orbit of an atom to another without traversing the interval in between, that an empty canvas or smears made by monkeys is a work of art, and that the clatter of falling garbage pails or a moment of silence is a work of music. And lest we should forget our recurrent example of the motion of the earth around the sun, contemporary philosophers assert that one cannot even be certain that the sun will rise tomorrow—that such a thing has no necessity, and will just "probably" occur.

The ability of such views to gain prominence already reflects an advanced state of philosophical corruption. Once established, they give the realm of ideas the aura of a dishonest game, a game that serious people are unwilling to play or to concern themselves with. At the same time, they open the floodgates to the dishonest. In the realm of economics, the establishment of such views has enormously encouraged the pressure groups and advocates of socialism, who have been enabled to propound their opposition to the teachings of economics under the sanction of an allegedly higher, more advanced "non-Euclidean economics." In addition, by depriving the intellect of credibility and substituting sophistry for science, their establishment has allowed demagogues to flourish as never before. The demagogues can count both on few serious opponents and on audiences not willing or able to understand such opponents. Thus, they have an

open season in propounding all the absurd charges against capitalism that I described earlier.

Economics by itself certainly cannot reverse this epistemological current. Even more than in the case of ethics, that must come mainly from within philosophy. But economics, or any other special science, can certainly make an important contribution to that reversal by refuting the irrationalists within its own domain and by establishing the principle that within its domain intelligible natural law is, indeed, operative. In refuting the theories of Keynes and similar authors, it can show that in economics there is no basis for the advocacy of irrational theories and that reason prevails. This perhaps may help to set a pattern for the same kind of demonstration in other fields.

Economics, moreover, is uniquely qualified to demolish the apparent conflict between theory and practice which today's intellectuals experience in connection with the undeniable failure of socialism and success of capitalism. The overwhelming majority of today's intellectuals, it must be kept in mind, believe virtually every point of the indictment of capitalism described earlier in this section. Thus, from their perspective, socialism should have succeeded and capitalism have failed. They had to expect that Soviet Russia, with its alleged rational economic planning and concentration on the building up of heavy industry, should have achieved the kind of economic eminence that Japan has achieved under capitalism, and have done so long ago. At the same time, they had to expect that the United States and Western Europe should have fallen into greater and greater chaos and poverty.

Yet, despite everything they believe, and think they understand, socialism has failed, while capitalism has succeeded. Being unwilling to admit that they have been wrong in their beliefs—thoroughly, devastatingly wrong—they choose to interpret the failure of socialism and success of capitalism as proof of the impotence of the mind to grasp reality, and now turn en masse to supporting the ecology movement and its assault on science and technology.⁴⁹ In this way, ironically, the failure of socialism and success of capitalism have played an important role in accelerating the growth of irrationalism.

In presenting a correct theory of capitalism and socialism—that is, in explaining why in reason capitalism must result in a rising productivity of labor and improving standards of living, while socialism must culminate in economic chaos and a totalitarian dictatorship—economics reunites theory and practice in this vital area. It thereby reaffirms the power of the human mind and removes the failure of socialism and success of capitalism as any kind of pretext for irrationalism.

6. Economics and Capitalism: Science and Value

This is not a book on philosophy. It is not its purpose to validate the philosophy of the Enlightenment with respect to the fundamental questions of metaphysics, epistemology, or ethics. It simply takes for granted the reliability of reason as a tool of knowledge and the consequent value of man and the human individual. It leaves to philosophers the job of convincing those who do not share these convictions. Its domain is merely the principles of economics and the demonstration that capitalism is the system required for prosperity, progress, and peace.

Nevertheless, one philosophical question that must be briefly addressed here is the assertion that science and value should be kept separate and distinct—an assertion that is often made by advocates of socialism and interventionism when they are confronted with the advocacy of capitalism. This book obviously flies in the face of that demand, for it consistently seeks to forge a union between the science of economics and the value of capitalism.

Despite the prevailing view, this procedure is perfectly sound. The notion that science and value should be divorced is utterly contradictory. It itself expresses a value judgment in its very utterance. And it is not only self-contradictory, but contradictory of the most cherished principles of science as well. Science itself is built on a foundation of values that all scientists are logically obliged to defend: values such as reason, observation, truth, honesty, integrity, and the freedom of inquiry. In the absence of such values, there could be no science. The leading historical illustration of the truth of these propositions is the case of Galileo and the moral outrage which all lovers of science and truth must feel against those who sought to silence him.

It is nonsense to argue that science should be divorced from values. No one who makes this demand has ever been able consistently to practice it. What it is proper to say is that science should be divorced from *mere emotion*—that it must always be solidly grounded in observation and deduction. Irrational emotion should not be confused with dedication to values, however.

The basis of the value of capitalism is ultimately the same as the basis of the value of science, namely, human life and human reason. Capitalism is the social system necessary to the well-being and survival of human beings and to their life as rational beings. It is also necessary to the pursuit of science—to the pursuit of truth without fear of the initiation of physical force. These are all demonstrable propositions. The advocacy of capitalism by economists, therefore, should be no more remarkable, and no more grounds for objection, than the advocacy of health by medical doctors.⁵⁰

Notes

1. For an account of the change that has taken place in the definition of economics, see Israel M. Kirzner, *The Economic Point of View* (New York: D. Van Nostrand, 1960).
2. I could also say that economics is the science which studies the production of wealth under a system of division of labor and monetary exchange, or under a system of division of labor and capitalism. (See below, p. 19, the first two paragraphs of Part B of this chapter.) Both of these statements would be correct, but they would also be redundant, because, as later discussion will show, a system of division of labor presupposes both monetary exchange and all the other essential institutions of a capitalist society. Finally, the expression goods and services could be substituted for the word wealth. This too would yield a true statement about what economics studies. But, as will be shown, a certain priority and emphasis must be given to wealth as opposed to services.
3. Secondly and peripherally to its study of the production of wealth under a system of division of labor, economics also studies the production of wealth under the absence of division of labor. It does so insofar as by so doing it can develop its theorems under simplifying assumptions that will enable it to shed light on the operations of a division-of-labor society, and insofar as by so doing it can place the value of a division-of-labor society in its proper light, by contrasting it with non-division-of-labor societies.
4. In the second century A.D., the Roman Empire extended from Syria in the southeast to the northern border of present-day England in the northwest. It circled the Mediterranean Sea, embracing Egypt and all of North Africa, and included all of Europe west of the Rhine, as well as present-day Romania and Turkey and all of Eastern Europe south of the Danube. Goods produced in the various regions of the Empire were consumed throughout the Empire. For example, pottery made in Syria was consumed as far away as England, and tin mined in England was consumed as far away as Syria.
5. Because of its primary application to government policy, it is understandable why the subject was originally known as political economy, which was its name from the time of Adam Smith to the last quarter of the nineteenth century, when the change to “economics” took place.
6. See below, pp. 473–498, 544–548, 559–580, and pp. 603–668.
7. I am indebted to von Mises for this view of what economics has to offer historians and journalists. Cf. Ludwig von Mises, *Epistemological Problems of Economics*, trans. George Reisman (Princeton, N. J.: D. Van Nostrand, 1960), pp. 27–30, 99–102.
8. Cf. Ludwig von Mises, *Socialism* (New Haven: Yale University Press, 1951), p. 402; reprint ed. (Indianapolis: Liberty Classics, 1981). Page references are to the Yale University Press edition; pagination from this edition is retained in the reprint edition.
9. On this subject, see below, pp. 462–498.
10. For elaboration, see below, pp. 42–49 and 542–559.
11. See the writings of Ayn Rand for a consistent elaboration of the “benevolent universe premise” across the entire range of human activity.
12. For a discussion of the ideas of Marx and Engels on “alienation,” see below, pp. 129–130.
13. See above, the discussion of mathematical economics on pp. 8–9. See also below, pp. 158–161.
14. See Bernard Siegan, *Economic Liberties and the Constitution* (Chicago: University of Chicago Press, 1980).
15. This section was inspired by and draws heavily on the content of a lecture delivered by Dr. Leonard Peikoff in Chicago, in May 1980, under the title “The Philosophic Basis of Capitalism,” before the Inflation and Gold Seminar of the US Paper Exchange/Tempor Corporation.
16. Ayn Rand, “Man’s Rights,” in Ayn Rand, *The Virtue of Selfishness* (New York: New American Library, 1964), pp. 124–125.
17. See below, pp. 27–28.
18. On these points, cf. Ayn Rand, “The Nature of Government,” in Ayn Rand, *Virtue of Selfishness*.
19. Cf. *ibid.*
20. In a fully consistent capitalist society, taxation itself would be of a voluntary nature. On this subject see Ayn Rand, “Government Financing in a Free Society,” in Ayn Rand, *Virtue of Selfishness*.
21. Again, cf. Ayn Rand, “The Nature of Government,” in *Virtue of Selfishness*.
22. See below, pp. 343–371, 513–514, 542–594 *passim*, and 938–942.
23. It should be realized that even if much of the savings individuals presently pay into the social security system were invested in housing, as they likely would be, those savings would indirectly still contribute to investment in factories and machinery. This is because savings would then not have to be withdrawn from financing factories and machinery to financing housing, as is presently the case because of the vast siphoning off of personal savings caused by the social security system.
24. The problem of the economic insecurity of prospective social security recipients (and of everyone else) is compounded by the fact that an inevitable accompaniment of the welfare state is fiat money, which makes all contractual obligations stated in fixed sums of money essentially meaningless. On these points, see below, pp. 925–926 and 930–931.
25. It should go without saying that the context taken for granted in the reference to anti-pornography legislation is one in which all the parties involved are freely consenting adults.
26. The following discussion is essentially an application of principles set forth by Ayn Rand in criticizing the use of the word *censorship* in reference to the actions of private individuals. Cf. Ayn Rand, “Man’s Rights,” in Ayn Rand, *Virtue of Selfishness*, especially pp. 131–134.
27. Cf. *ibid.*, pp. 128–130.
28. *Ibid.*
29. See below, pp. 375–387 and 238. The contrasting meanings of the right to medical care are discussed on p. 380. Concerning this last subject, see also George Reisman, *The Real Right to Medical Care Versus Socialized Medicine*, a pamphlet (Laguna Hills, Calif.: The Jefferson School of Philosophy, Economics, and Psychology, 1994).
30. For further discussion of the distortions introduced into the concept of freedom of labor and present in the notion of “wage slavery,” see below, pp. 330–332.

31. I am indebted to von Mises for the substance of this discussion. See Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 734–736.

32. Concerning the fact that the division of labor originates on the basis of differences in human abilities and in the conditions of people's natural surroundings, see von Mises, *Socialism*, pp. 292–293.

33. On the fact that money originates in the self-interested actions of individuals, see Carl Menger, *Principles of Economics* (Glencoe, Ill.: The Free Press, 1950), pp. 257–262. See also below, pp. 506–517.

34. These factors also operate to create a steadily growing supply of useable, accessible natural resources. See below, pp. 63–67.

35. See below, pp. 123–133.

36. See above, p. 19, the opening paragraph of Section I of Part B, of the present chapter.

37. See below, pp. 938–941.

38. In most of the world, unfortunately, the history of private property is not so simple. Again and again, owners were forcibly dispossessed by foreign invaders, by civil wars and revolutions, and by other expropriations carried out by governments. Nevertheless, one of the things that later discussion will show is that even where holdings of private property can be traced back to acts of force, the operations of a capitalist society steadily wash away these stains. Once a few generations have gone by, during which private property no longer passes by force, but by purchase, the result is virtually the same as if it had never passed by force. For a discussion of this point and also of the alleged injustices committed specifically against the American Indians in the process of appropriating land in North America, see below, pp. 317–319. See also Ludwig von Mises, *Socialism*, p. 504.

39. In the last generation, Japan, Taiwan, and South Korea have achieved even more rapid rates of economic progress than the United States did in its era of greatest progress. But the rapidity

of their advance is largely the result of being able to take advantage of the enormous heritage of innovations pioneered by and bequeathed to them by the United States.

40. See below, pp. 99–106.

41. The leading manifestation of this worldview is the Marxian exploitation theory and the “liberal” political agenda that rests on it. See below, pp. 603–604.

42. The nature of these fallacies, along with most of their leading manifestations, has been brilliantly dissected by Henry Hazlitt, *Economics in One Lesson*, new ed. (New Rochelle, N. Y.: Arlington House Publishers, 1979), and by Frederic Bastiat in his *Economic Sophisms*, trans. Arthur Goddard (New York: D. Van Nostrand, 1964).

43. See below, pp. 618–663, 930–937.

44. On this subject see below, pp. 712–714.

45. See von Mises, *Human Action*, pp. 258–259. Also, see below, pp. 263–264.

46. Cf. Henry Hazlitt, *Economics in One Lesson*, pp. 15–19.

47. Among the most important and comprehensive writings on the subject of irrationalism and its destructive influence are those of Ayn Rand, virtually all of whose works shed profound light on it. See, for example, *Atlas Shrugged* (New York: Random House, 1957) and the title essay in *For the New Intellectual* (New York: Random House, 1961). See also the book of her leading intellectual disciple Leonard Peikoff, *The Ominous Parallels: The End of Freedom in America* (New York: Stein and Day, 1982). The works of von Mises also stress the destructive influence of irrationalism in all matters pertaining to economics and capitalism and are extremely valuable in this regard. See in particular, *Human Action* and *Socialism*.

48. J. M. Keynes, *The General Theory of Employment, Interest, and Money* (New York: Harcourt, Brace, 1936), p. 129.

49. See below, pp. 99–106.

50. For a philosophic demonstration of the wider union of fact and value, see the excellent essay “Fact and Value” by Leonard Peikoff in *The Intellectual Activist* 5, no. 1 (May 18, 1989).

CHAPTER 2

WEALTH AND ITS ROLE IN HUMAN LIFE

1. Wealth and Goods

Wealth is material goods made by man. It is houses and automobiles, piles of lumber and bars of copper, steel mills and pipelines, foodstuffs and clothing. It is also land and natural resources in the ground insofar as man has made them useable and accessible. Man, of course, does not make the material stuff of land and natural resources, but he certainly does create their character as wealth.¹

Air, sunlight, rainfall, and wind are also material goods. But insofar as they come to us automatically, without any need for labor or effort on our part to cause their existence or our benefit from them, they are outside the province of economic activity and of economics. They are nature-given conditions that automatically benefit us; historically, they have been described as *free goods*. Economics deals only with those goods which are the object of economic activity, that is, which man needs to produce in some sense—goods whose existence or beneficial relationship to his well-being he needs to cause in his capacity as a thinking being, that is, on whose behalf he must expend labor or effort. Such goods are *economic goods*.² In saying that wealth is goods, we refer only to economic goods; we exclude free goods.

Some implications of the fact that wealth consists of goods must be named.

Wealth is not at all synonymous with money or monetary value. The wealth produced in an economic system and the total monetary value of that wealth are separate and distinct phenomena. The one can increase without

the other. More wealth can exist totally apart from more money. More wealth produced in the form of ordinary commodities, like steel, sugar, automobiles, and so on, without any increase in the supply of money, is nonetheless more wealth; but in such circumstances it results in correspondingly lower prices, and no increase in the total monetary value of commodities. By the same token, more money and more monetary value can exist totally apart from more wealth. This happens almost every day under a system of fiat paper money, where the supply of money is determined by the wishes of the government, irrespective of the supply of goods. In such circumstances, the effect of the additional money is simply to raise prices.

A connection between the quantity of money and the amount of wealth would exist only if money consisted of gold or silver. Even then, it would be a highly imperfect connection. Under such circumstances, an increase in the supply of gold or silver would constitute both an increase in the supply of money and an increase in the supply of wealth insofar as more gold and silver in their capacity as industrial materials meant more wealth. A further connection would exist insofar as increases in the supply of money under such circumstances tended to exist as the by-product of general improvements in the ability to produce, that is, insofar as a larger supply of gold or silver was the result of improvements in machinery, transportation, and so forth, having wider application than merely to the mining of the precious metals. In reality, all the popular measures of the production of wealth expressed in terms of totals of money, such as Gross Domestic

Product (GDP) (formerly Gross National Product or GNP) and National Income, are nothing but indicators of the quantity of money, not the physical volume of goods produced.³

Stocks, bonds, and bank deposits are also not wealth. They are claims to wealth—to the plant and equipment and inventories of firms issuing the stocks or bonds or borrowing from the banks; to the houses or automobiles of the consumers who have borrowed; or, in the case of unsecured loans, to the equivalent of the goods that would otherwise be purchasable by the borrowers with their incomes.

Nor is the market value of licenses, or legal rights in any form, wealth; this includes the market value of perfectly proper legal rights such as patents and copyrights. Government licenses, such as liquor licenses, derive their market value from the privilege they confer on their holders to *restrict the production of wealth* and thereby artificially to increase the incomes of the license holders.⁴ While patents on new inventions and copyrights on other new intellectual creations greatly contribute to the production of wealth by providing incentives to the development of new ideas underlying the production of wealth, neither the ideas themselves nor the patents and copyrights which protect and promote them are wealth. The ideas are preconditions to the production of wealth, but not wealth itself. And the patents and copyrights derive their market value from the fact that they make it possible for the intellectual creators of new and additional wealth to benefit from their contributions by temporarily limiting the increase in wealth that their intellectual contributions bring about. When patents and copyrights expire, the supply of wealth further increases at the same time that the market value of the patents and copyrights vanishes.⁵

Finally, the labor of people, and their persons, while also indispensable preconditions to the production of wealth are never themselves wealth, but merely preconditions to the production of wealth. This is true even in a society in which slavery exists. In such a society, the fact that slaves possess market value no more qualifies them as wealth than the fact that government licenses restricting production possess market value qualifies them as wealth. Indeed, slavery reduces the production of wealth far more than do restrictive government licenses: it attacks production at its very root by depriving people of the incentive to produce.⁶

Thus, wealth must be distinguished from the wider concept of property possessing market value. Property possessing market value that is not itself wealth exists, as we have seen, in such forms as various legal rights to wealth, such as stocks and bonds, and in various legal rights, proper or improper, to restrict or limit the produc-

tion of wealth, such as government licenses and patents and copyrights. Property that is not wealth—that, indeed, is the destroyer of wealth—but that nonetheless possesses market value is what exists in the case of slavery.

The meaning of wealth depends on the meaning of goods. More or less following Menger, the founder of the Austrian school of economics, we can define goods—economic goods—as *things which are recognized as capable of satisfying human needs, requiring the expenditure of labor or effort in order to be produced or enjoyed, and over which one has sufficient command gainfully to direct them to the satisfaction of one's needs.*⁷ In other words, goods are things actually capable of benefiting us, that is, of doing us personal good, provided that we make the necessary effort to secure their benefit. Our wealth is the collection of material goods which we possess or against which we hold enforceable claims.⁸

Things which have the power to satisfy our needs but which we do not recognize as possessing that power are not goods and do not form part of our wealth. For example, before the second half of the nineteenth century, petroleum was not a good; before the twentieth century, uranium was not a good. People did not know the beneficial properties of petroleum or uranium and thus did not know how to use them for anything. Thus, at the time, such things could do them no actual good and were therefore not goods and not a part of wealth. (The only circumstance in which a thing could do us good without our being aware of its beneficial properties, and thus without our having to take action based on such awareness, would be if its benefit came to us automatically, that is, if it were a free good. For a thing to be an *economic* good, it is essential that we possess awareness of its beneficial properties.)

In the same way, even if technological knowledge exists concerning the usefulness of a given type of mineral, all of the specific deposits of the mineral which are as yet undiscovered are not goods and do not constitute wealth. They too can do us no actual good in such a case. Further, things are not goods and do not constitute wealth whose useful properties and specific locations are known, but over which we lack sufficient command to direct them to the satisfaction of our needs. For example, iron on Mars, or even fifty miles down in the Earth, is not a good and not wealth, even if we are aware of its specific location, given our present inability to gain access to it. By the same token, water in the United States is not a good to someone wandering in the Sahara. Manufactured products too are not goods to those who have no knowledge of their existence or cannot gain access to them.

Finally, things are not goods and do not constitute wealth even if their useful properties and specific locations are known and even if we have sufficient command

over them to direct them to the satisfaction of our needs, if we cannot *gainfully* direct them to the satisfaction of our needs. For example, vast stretches of land in the United States which could be used to grow crops if someone decided to do so, are not actually goods and not wealth, because their potential could be exploited only by withdrawing capital and labor from other employments where the product of the capital and labor is greater. (These other employments could be more productive farmland, or nonagricultural employments whose product is more important than an addition to the supply of farm products.) The use of such land to grow crops would thus not achieve our actual good, all things considered, but would inflict a loss in comparison with what could be produced without its use. Thus, such land does not constitute a good and is not part of wealth. (It is possible, of course, that such things, presently not goods, could someday become goods and thus wealth—if, for example, the costs of exploiting them could be reduced, or if a growing population provided labor and capital that had no better alternatives to which to be applied. To some extent, such things may be valued as goods and count as wealth in the present, in anticipation of their being able to accomplish actual good in the future.)

Just as the beneficial properties of things can fail to be recognized, it sometimes happens that beneficial properties are ascribed to things which do not in fact possess them, such as the beneficial properties some people ascribe to rabbit's feet, tarot cards, and so on. We can join with Menger in characterizing such things as "imaginary goods." It is not necessary, however, for economics to devote any special consideration to such goods beyond acknowledging the fact of their existence. This is both because they constitute unimportant exceptions and because the economic principles that apply to such goods, such as the laws of price determination, are the same as that apply to genuine goods.

Again following Menger, we can divide goods into various orders, corresponding to their closeness to, or remoteness from, the satisfaction of our needs and wants. Goods that stand in a direct causal relationship to the satisfaction of our needs and wants can be described as goods of the first order. These are the things that benefit us directly and that are, therefore, directly good. For example, the food we eat, the clothes we wear. Those goods, in turn, that are necessary to the production of goods of the first order can be described as goods of the second order. For example, the ingredients and implements required to prepare a meal; the cloth, sewing machines, and thread required to produce clothes. Similarly, those goods that are necessary to the production of goods of the second order can be described as goods of the third order, and so on. The advantage of this termi-

nology is that it highlights the fact that the source of the goods-character of things is ultimately *within us*. Goods derive their character as goods by virtue of their ability to benefit human beings. Goods-character radiates outward from people to things and touches first those goods which we categorize as goods of the first order, second, those which we categorize as goods of the second order, and so on.⁹

2. Economics and Wealth

The fact that economics is a science of wealth was taken for granted by the classical economists in the nineteenth century. Economics' focus on wealth has been challenged in the twentieth century, however, and a large majority of economists now downplays its special importance in the subject.

One challenge is constituted by the frequent assertion that our economy has become a "service economy" rather than an economy which concentrates on the production of goods. The basis of this assertion is the fact that more than half of the working population is now employed in rendering services rather than producing goods.

This service-economy argument against the focus on wealth is superficial, for the following reason. Not only are agriculture, mining, construction, and manufacturing all engaged in the production of goods, but also *all of the so-called service industries center on goods*. Retailing and wholesaling—service industries—are the retailing and wholesaling of *goods*. Cleaning, repair, and maintenance services are the cleaning, repair, and maintenance of *goods*. Transportation and communications are largely transportation of, and communications concerning, *goods*. Banking, finance, insurance, and advertising are services performed overwhelmingly in connection with facilitating the production, distribution, or ownership of *goods*.

Those services that are performed not as auxiliaries to the production, distribution, or ownership of goods—services such as passenger airline travel for vacationers, personal communications, personal medical, legal, or grooming services—vitaly depend on the use of goods in their rendition. There could be no passenger airline travel without airplanes and airports; no telephone service without telephones and telephone exchanges; no mail service without post offices and delivery trucks; precious few medical services without drugs, hospitals, laboratories, and all manner of equipment; precious few legal services without courthouses, law offices, law books, law schools, memo pads, and so on; and precious few grooming services without scissors, razors, hair dryers, and the like. The rendition of personal services falls within the sphere of economics insofar as the providers

of such services render them *for the purpose of acquiring wealth*. As will be seen, in a division-of-labor society this refers to the rendition of such services for the purpose of earning money. Thus, the services of personal physicians, personal attorneys, barbers, and the like come within the sphere of economics insofar as they are performed for money, which is the means by which these parties obtain wealth.

It is true, of course, that there could be no wealth without the rendition of services—above all, the performance of labor. But this does not give services an equal position with wealth in economics. Although economics is concerned with services, it is so only insofar as they are necessary to the production, enjoyment, or acquisition of wealth, or depend on the use of wealth. Economics is not at all concerned with the rendition of services apart from their connection with wealth. For example, when two people hold an interesting conversation, they are rendering a service to each other. But economics is not concerned with activities of this nature except insofar as they can be connected with wealth.

It could be argued that the direct exchange of services for services also sometimes falls within the sphere of economics—for example, an exchange of French lessons for mathematics lessons, in which the rendition of each service is performed as the conscious, explicitly agreed-upon requirement of receiving the other. Even in such cases, what brings the rendition of the service within the purview of economics is ultimately a connection to wealth. This is so because what makes exchange itself a vital economic phenomenon, central to the studies of economics, is the fact that in a division-of-labor society the production and enjoyment of wealth requires it, as the means of bringing goods from their producers to their consumers.¹⁰

The second challenge to economics' focus on wealth is the mistaken claim that economics is a science of choices rather than a science of wealth—a science which studies the “allocation of scarce means among competing ends.”¹¹

This contention rests on a logical fallacy. It does not see that what gives rise to economics' study of choices and its concern with the allocation of scarce means among competing ends is the fact that people have a virtually limitless need for *wealth* but only a limited capability of satisfying that need at any given time. Thus, people must choose which aspects of their need for wealth are to be satisfied and which are not. Economics studies the determinants of human choice only insofar as they concern choices of how to spend incomes that are of necessity limited, and only insofar as they affect the attraction of capital and labor to the production of some goods rather than other goods. In other words, it studies

the issue of choices for no other reason than that it is necessary to do so as part of its study of the production of wealth under a system of division of labor.

To claim that economics is on this account a science of human choices rather than of wealth is to confuse an aspect of the science with its totality. To adopt this view is to be led to ignore all the really crucial matters that economics deals with and to seek esoteric extensions of the subject that have nothing whatever to do with its actual nature. Fortunately, those who adopt this view are highly inconsistent in its application and generally continue to devote most of their attention to the serious business of economics and leave the alleged necessity of extending the subject beyond the domain of wealth as a task to be carried out in the indefinite future.¹²

3. The Limitless Need and Desire for Wealth

The leading propositions laid down in Chapter 1 were that economics is the science that studies the production of wealth under a system of division of labor and that capitalism is the essential requirement for the successful functioning of a division-of-labor society, indeed, ultimately for its very existence. It is implicit in these propositions that the ultimate source of the importance of the division of labor and capitalism, and of the science of economics, is *wealth*. This is because, in the last analysis, the division of labor, capitalism, and the science of economics are all merely means to the production of wealth.

Nevertheless, many philosophers and religious thinkers have held that the production of wealth serves only a low order of needs of secondary importance and that concern with its production beyond the minimum necessities required for the sustenance of human life is evil, immoral, and sinful by virtue of elevating low material values to the place properly reserved only for the pursuit of noble spiritual values. If these beliefs were correct, then economics would at best be a science of secondary importance and preoccupation with it by serious thinkers would be a mark of perversity.

In the face of such attitudes, it is incumbent upon economics to justify itself by providing philosophical validation for the production of wealth being a central, continuing concern of human existence. In other words, economics must explain the role of wealth in human life beyond that of the food, clothing, and shelter required for immediate sustenance. It is necessary to show how the continuing rise in the productivity of human labor made possible by the division of labor and capitalism serves *objectively demonstrable human needs*—to show, indeed, why there is no limit to man's need for wealth. Only on the basis of an objectively demonstrable need for

wealth without limit is there a full and secure foundation for the need for the division of labor and capitalism and the continuous economic progress they bring, and for the science of economics.

Human Reason and the Scope and Perfectibility of Need Satisfaction

Man's need for wealth is limitless because he possesses the faculty of reason. The possession of this faculty both radically enlarges the scope of man's needs and capacities in comparison with those of any other living entity and, at the same time, makes possible continuous improvement in the satisfaction of his needs and in the exercise of his capacities. Considered abstractly, man's possession of reason gives him the potential for a limitless range of knowledge and awareness and thus for a limitless range of action and experience. Man's mind can grasp the existence both of subatomic particles and of galaxies, and of everything in between. It observes all manner of patterns and similarities and differences, of which no other form of consciousness is capable. Thus, the potential is created for man to act over a range extending from the subatomic level to the remotest reaches of outer space, and to experience all that his mind enables him to discern and enjoy in the totality of the universe.

Material goods—wealth—are the physical means both of acting in the world (for example, automobiles and airplanes, tools and machines of all kinds) and of enjoying the experiences of which man is capable (for example—in addition to many of the goods in the preceding category—works of art and sculpture, landscaped grounds and gardens, beautiful homes and furniture). They are the instrumentalities of man's action and objects of his contemplation. The potential of a limitless range of action and experience implies a limitless need for wealth as the means of achieving this potential. Man needs wealth without limit if he is to fulfill his limitless potential as a rational being in physical reality.

This abstract principle can be illustrated in a wide variety of forms, starting with the contribution of additional wealth to the improved satisfaction of man's elementary needs for nutrition and health. Because man possesses reason, and is thus able to abstract, form concepts, and think conceptually, his mind is able to grasp connections spanning generations and continents between his material well-being and the physical state of the world. Thus, for man, functioning on the conceptual level, the satisfaction just of the needs for nutrition and health implies a practically limitless need and desire for wealth: in the form of canning and freezing facilities, a modern transportation and communications system, a farm-equipment industry, and everything that is necessary to the existence of these things, such as the steel, oil,

and coal industries, the transportation and communications equipment industries, and so on. All such wealth is necessary to an adequate quantity and sufficient variety of food to meet man's nutritional needs. Likewise, man's need for health further implies a need not only for medicines, hospitals, and all manner of diagnostic and therapeutic equipment and everything necessary to their existence, but extends even to such seemingly unrelated things as automobiles and space travel: the former made possible the ability of people to live in the fresh air of the suburbs and also the modern ambulance; the latter holds out the possibility of such things as recuperation from heart disease in an environment of reduced gravity.

Reason gives to man the ability to use wealth progressively to enhance the exercise of the capacities he shares in common with lesser species. For example, man shares with animals the capacity for locomotion. Animals can do no better than rely on their unaided legs. Man domesticates the horse, the elephant, and the camel. He produces shoes and builds roads, rafts, and sailing vessels. He goes further and invents the railroad, the steamship, and the automobile; and then the airplane and the rocketship. Similarly, man shares with the animals the capacity to see and hear. Animals can do no more than rely on their unaided eyes and ears, but man produces telescopes, microscopes, and stethoscopes; television sets and radios; eyeglasses and hearing aids; X-ray machines and computers; motion pictures and VCRs; and phonographs, compact-disk players, and tape recorders.

As noted, the fact that man is the rational being also gives him a wider range of capacities than is possessed by any of the lesser species. Because man is the rational being, he is able to pursue such activities as music, art, science, and athletics. He is able to form relationships with others which are maintained even though the parties may be separated by great distances and for long intervals of time. It is the nature of man's brain that enables him to integrate separate sounds into harmonies and melodies, to grasp representations and thus the meaning of a painting, to pursue science, to follow the system of rules of a game of sport, and to maintain an awareness of others from whom he is separated by time and distance. These are feats of which an animal's brain is incapable. In the pursuit of all of these additional activities made possible by the possession of reason, wealth either is absolutely indispensable or, at a minimum, enormously contributes to the performance and enjoyment of the activity.

Wealth contributes to music when it takes the form of musical instruments, music books and scores, concert halls and conservatories, radios, phonographs, and tape recorders. If music were deprived of the existence of these forms of wealth, the activity would be reduced to

the unaided, untrained, and largely unheard singing of the human voice. In the absence of wealth in the form of brushes, paints, and canvases, of museums, schools, and books of art, art would be reduced to primitive drawings on the walls of caves. In the absence of wealth in the form of scientific equipment, laboratories, universities, and libraries, science could not be pursued. In the absence of wealth in the form of playing fields, athletic equipment, stadiums, and radio and television sets, athletic events and the enjoyment derived from them would suffer a radical decline. In the absence of wealth in the form of pens and paper, post offices, telephones, automobiles, railroads, ships, and planes, friendships and other human relationships could not be maintained over long distances.

On the basis of these observations, it is obvious that the ancient prejudice that man's desire for wealth serves his "lower" needs is absurd. Wealth is the material means of carrying on virtually *every* human activity and of serving virtually all of man's needs. It is man's means of acting in accordance with his human potential.

Moreover, even the wealth that does serve man's "lower" needs, such as, presumably, his needs for nutrition and elimination, also reflects his nature as a rational being, in ways beyond those already described. When man serves his "lower" needs, he does so in a manner that is unique to him—in a manner that reflects the distinctive nature of his consciousness. For example, when man eats, he does not do so in the manner of an animal, indifferent to his surroundings. On the contrary, he desires such things as tables and chairs, table linen, china, silverware, and so on. He is also highly sensitive to the preparation of his food and to the combinations in which it is served. When man eliminates, he desires the existence of such things as indoor plumbing and privacy. In such activities, the nature of man's consciousness requires the incorporation of psychological and aesthetic elements into the satisfaction of what in animals are merely physical needs. For man, at least in his waking hours, there is probably no such thing as a purely physical need. Man's physical needs are intimately connected with his psychology as a rational being—as a being aware of such things as patterns and harmonies and dissonances in shapes, sounds, and colors, and possessing the need to organize his activities and control the functions of his body. In everything he does, man can be aware of his own emotional responses and can distinguish between aesthetic elements which enable him to have a more enjoyable or a less enjoyable emotional response.

Thus, the aesthetic element enters into the satisfaction of virtually all of man's needs. It leads him to desire not just clothing and shelter, but clothing and shelter with

style and beauty. It leads him to desire not just "transportation," but automobiles with chrome trim and whitewall tires. Matters of design and appearance feature prominently in all consumers' goods where men are free to choose.

Closely related to man's need for aesthetic satisfaction is his need for novelty and variety, which need also emanates from the rational nature of his consciousness. The lower animals do not become bored with the repetition of the same routine. Man does. The nature of man's consciousness enables him to appreciate differences of a kind of which animals show no apparent awareness, and seems to require that he periodically experience such differences. Thus, whereas animals are content to eat the same food day in and day out, man requires a variety of food. Man experiences a sense of intellectual refreshment when he breaks his routine and takes a vacation or a weekend off. He also experiences a sense of intellectual refreshment in the introduction and possession of new goods, and with the coming of style changes.

Thus, the appearance of almost every new "gadget" is an occasion for a kind of excitement: it is a thrill for a rational consciousness to see such new products appear (each in its day) as automobiles, airplanes, refrigerators, radios, television sets, pocket calculators, computers, and so on. The purchase of such goods is almost always an occasion for special pleasure, because it provides something new and valuable to experience. Even the replacement purchases of such goods are usually a source of pleasure, because further improvements have usually been made in them, and because of style changes. Changes in style, whether in automobiles, clothing, or furniture, are a source of intellectual refreshment and pleasure, because they provide a sense of the new and different.

It must be stressed that man's desire for novelty and variety stands in the service of his life. The principle is very similar to that of the pursuit of scientific knowledge, where the motive is curiosity and the effect is all manner of practical applications that could not have been foreseen in advance. In just this way people originally desired automobiles not as a practical means of transportation, but as an object of amusement. Yet this desire led to the growth of the automobile industry and to the transformation of the economic system. A similar course of development occurred in the case of electric light and power, and telephones and television sets, and now seems to be under way in the case of home and personal computers.

Even if no practical applications ever result directly from the things desired, their being desired produces practical results. For example, a great industrialist's motive in earning additional millions on top of those he already has may be merely to add to his collection of fine paintings and statues. But in pursuing this motive, the

industrialist is led to introduce products and methods of production that enable the average person to obtain such things as more and better food, clothing, and transportation.

Man's life gains incalculably from the fact that his activities are not limited to the "practical," but are undertaken largely for the sheer pleasure of experiencing the new and different and the corresponding expansion of his own powers required to accomplish it. For this leads him to do things that have practical results which would otherwise be impossible for him to obtain. In effect, reason serves man's life in being free to serve itself. Although man's life may not need every particular object of his desire for novelty and variety, it very much does need the existence of his desire for novelty and variety.

On the basis of the existence of an objectively limitless need for wealth, there is no limit to man's desire for wealth. The occasional cases that exist of individuals in whom the desire for additional wealth is totally repressed are comparable in their frequency and significance to the cases of individuals in whom sexual desire is totally repressed. These cases are rare indeed. Even medieval monks, for example, thoroughly committed to the doctrine of asceticism, were torn by the temptation for material things. The truth lies with Adam Smith, who observed that "the desire of food is limited in every man by the narrow capacity of the human stomach; but the desire of the conveniences and ornaments of building, dress, equipage, and household furniture seems to have no limit or certain boundary."¹³

To translate Smith's observation into contemporary terms, we can observe as the overwhelming norm such things as that the man who has no automobile would like to be able to afford one. The man who has an automobile would like to be able to afford a newer, better one. The man who has several new automobiles of the highest quality would like to be able to afford a yacht or a plane. If he is rich enough to afford both a yacht and a plane, then he would like to be able to afford a yacht on which the plane can land, and so on. Similarly, the man who has a small house or apartment would like to be able to afford a larger one. If he has a large house or apartment, then he would like a more luxurious one—perhaps with a swimming pool or tennis court, or both; and with finely landscaped grounds. And he would probably like to have more than one house or apartment—perhaps a hunting lodge in Maine, a winter home in Palm Beach, an apartment in Paris, or, indeed, all three of them. The more one has, the more one wants.

The fact that both the need and the desire for additional wealth are limitless for all practical purposes does not mean, however, that people automatically act to satisfy that need and desire. It is certainly possible for the

need and desire for additional wealth to fail to result in the production of additional wealth, let alone in continuous economic progress. Indeed, history and most of the world around us are characterized by stagnation and poverty. The mere possession of a need or desire is never sufficient to ensure that the need or desire will be satisfied. In the absence of the influence of a rational philosophy establishing limited government and economic freedom and inculcating such convictions as that the material world has both reality and primacy, that it is intelligible, and that hard work pays, man is not able to devote himself sufficiently to the production of wealth.¹⁴

In such conditions, man desires more wealth than he possesses, but his desire is not strong enough or consistent enough to enable him actually to go and produce additional wealth. And if it is strong enough to induce him to increase his production, he is again and again stopped from doing so because of the initiation of physical force by others. Even when the barrier of physical force temporarily relaxes and some individuals are able to make some improvements, the absence of a rational philosophy precludes the development of science. It also precludes the establishment of sufficient freedom to make possible the development of the division of labor and the other capitalistic institutions necessary to the continuous increase in wealth.

As a result, despite the existence of both a need and a desire for additional wealth on the part of those affected, we witness such phenomena as masses of people dying of starvation, yet unable—indeed, sometimes even unwilling to expend the effort—to produce additional food. We witness primitive people delighted with the gift of mirrors and trinkets of all kinds, not to mention transistor radios and bicycles, yet continuing to live under essentially the same conditions as their remotest ancestors.

Progress and Happiness

The fact that the need and desire for wealth are limitless does not mean that when people devote themselves to satisfying that need and desire, as in the nations of modern capitalism, they go through life with a sense of endless frustration, seeking more than they can ever hope to obtain. The normal man, if he lacks an automobile, does not actively desire a yacht. He actively desires merely an automobile. His desire for a yacht lies dormant until such time as he already has acquired one or more high-quality automobiles. The limitless desire for wealth, in other words, becomes active only step by step. It manifests itself in an active desire for things that are merely one or two steps beyond our reach at the moment. It leads us to exert ourselves and extend our reach. And then, as we succeed, desires previously dormant become active, or totally new desires are formed, and we are led

to exert ourselves and extend our reach still further. Thus, the limitless desire for wealth impels us steadily to advance.

Oriental philosophy and some schools of thought in the contemporary Western world claim that the fact that our desires will always be a step ahead of our possessions shows the futility of our efforts—that, instead, we should seek to rid ourselves of our desires and be content forever with some minimum of wealth. Such teachings are utterly mistaken, and their influence helps to account for the stagnation and poverty that exist in the world. They view the excess of our desires over our possessions as a source of discontent and unhappiness. Actually, this excess is the root of our ambitiousness and our rising to meet challenges. It is what impels us to progress, and, as such, is an essential element of our happiness.

It should be realized that as rational beings we are also progressive beings. Progress is the corollary of the continuous application of reason. Any individual who continues to use reason—who continues to think—necessarily comes to know more and more, and thus to be capable of accomplishing more and more. If a society is characterized by continuous thinking from generation to generation, and if its educational system works—that is, if it succeeds in transmitting to the rising generation the essentials of the knowledge discovered by all the preceding generations—then the general body of knowledge in the society is progressive, and thus the society as a whole is capable of accomplishing more and more. Progress is the natural result of the use of reason as a constant.

If our happiness depends on living in accordance with our nature as rational beings, then our happiness and progress are inseparably connected. The fact that our desires will always be ahead of our ability to satisfy them is not a cause of unhappiness. It is the inducement to the steady exercise of our reason, to our living in accordance with our nature, which is indispensable to our happiness. Our happiness does not come from the existence of desires satisfied, but from the steady upward climb itself—from the process of continuing to think and solve problems and to become capable of accomplishing more and more. In other words, progress is a source of happiness. In the lives of scientists, inventors, businessmen, engineers, and managers, progress is the obvious focal point of thinking, planning, and problem solving. It is also what necessitates that the average worker make himself capable of continuing to think and learn throughout his life, so that he can acquire the new skills necessary to adapt to the changing requirements of production. Thus, progress is what helps to elevate even the average man of modern Western civilization into a thinking, literate being possessing an intellectual life incomparably superior to that of previous eras. If happiness depends

on the possession of a sound, active mind, progress fosters happiness.

A further aspect of the connection between progress, reason, and happiness must be mentioned. As rational beings, we are able to be aware of the future: the future has reality for us in the present. To be able to look forward to a better future enables us to bear considerable hardship in the present without complaint, even cheerfully. But to look to a future of unrelieved hardship, or, worse, a future that holds out the prospect of even greater hardship, makes hardship in the present more difficult, if not impossible, to bear. Indeed, the prospect of impoverishment in the future deprives one of the ability to derive pleasure even from the possession of substantial wealth in the present, for the shadow of such a future must hang over whatever enjoyment one might have in the present. Thus, the prospect of progress, as well as the process of achieving it, contributes to our happiness.

The Objectivity of Economic Progress: A Critique of the Doctrines of Cultural Relativism and Conspicuous Consumption

According to the widely held doctrines of cultural relativism and conspicuous consumption, the concept of economic progress can have no objective meaning.¹⁵ These doctrines hold, for example, that our preference for automobiles over horses, or for radios and television sets over jungle tom-toms, is a matter of social and cultural conditioning. It is allegedly the result only of the fact that in this particular culture it happens to have been instilled in people—for no really good reason—that it is desirable to own such goods as automobiles and television sets. Accordingly, people supposedly want to own such goods not because it really is desirable to own them in any objective sense, but merely that they may conform to what is expected of them in this culture. They allegedly want to own them as a source of *prestige* in the eyes of others.

The essential meaning of these doctrines can be grasped by realizing that what they imply is that people want to own television sets not because they want to watch the television sets, but because they want to be *seen* watching them—or because they were told to do so by the advertisers. Not the actual consumption of goods is important, we are told, but the “conspicuousness” of their consumption. Thus, the only real significance of television sets or any of the other “gadgets” of capitalist society is supposed to be their significance in the eyes of others. In a different culture people allegedly derive equal satisfaction from appearing before others with a ring through their nose, and in the society of the future (or at least as many people conceived the future until very recently) they will allegedly do so by wearing a chest full

of medals proclaiming them as heroes of socialist labor.

Thus, according to these doctrines, there is no reason to believe that people's preferences in a modern, capitalist society are any better grounded than those of people in any other type of society, or that a modern, capitalist society is in any objective sense superior to any other society. There is thus allegedly no basis for believing that what has been accomplished in a modern, capitalist society is in any objective sense progress.

Now what is wrong with these doctrines is that they omit any consideration of man in relation to the physical world. For them, the most important thing in human life is the mere approval or disapproval of other people, which is thought to constitute an ultimate standard, incapable of being subjected to further evaluation. But the truth is, of course, that the primary issue in human life is man's relation to the physical world. It is there and there alone that man must live or die, irrespective of the culture in which he lives. And how man succeeds in relation to the physical world provides an objective standard by which to judge the value of cultures. The examples of automobiles and television sets can serve to illustrate this point.

It is not true that our preference for the automobile over the horse is arbitrary, based on nothing more than social and cultural conditioning. It is based on our nature both as animate beings possessing the capacity of locomotion, and as rational beings capable of enlarging all of our physical capacities. We call the automobile an advance over the horse by the same standard by which we call the domestication of the horse an advance over possessing merely our unaided legs, and by the same standard by which we value the possession of our legs themselves. Namely, it extends our range and power of locomotion. If the automobile were not an advance over the horse, then the horse would not be an advance over our unaided legs. And, on the basis of such reasoning, the very possession of legs themselves could not be considered better than not possessing them. The automobile is an advance over the horse, therefore, for the same reason that it is better to have legs than not to have them.

Similarly, we call the telegraph an advance over the tom-tom, and radio an advance over the telegraph, because they increase the efficacy of our sense of hearing. The one enables us to hear sounds coming from a greater distance; the other, sounds from a greater distance as well as a greater range of sound. Thus, we value the radio over the telegraph, and the telegraph over the tom-tom, by the same standard as we value our sense of hearing itself. We call television an advance over radio for the same reason that we value the possession of eyes and ears together over the possession of ears alone. We call color television an advance over black and white, for the same reason that

we value normal vision over being colorblind.

The advances in our goods represent extensions of our power to use our limbs, senses, and minds to accomplish results. In effect, they magnify the power of these vital attributes of our persons. They are advances by the standard of the value of these attributes, and thus by the standard of the value of our persons.¹⁶

It may be that there are cultures in which people regularly grow up incapable of appreciating the value of economic advances. It may be that in this culture there are some people who really do not understand what our advances are all about and who see no better reason for valuing them than that of conforming to the expectations of others. The existence of such people and of such cultures proves not that our advances are not advances, but only that there are people with a gross deficiency of understanding, and cultures that are highly destructive of the capacity for understanding.

This discussion has major bearing on the fact that in American society, the earning of wealth has traditionally been the leading source of prestige. The objective fact underlying such prestige is that the earning of wealth benefits one's life by enabling one to do more. Thus, it *deserves* to bring prestige, by the standard of human life as a value. It is a great tribute to the culture of the United States that it is to such activity that it has accorded prestige.

It must also be pointed out that the attempt to reverse cause and effect, and to take prestige as the starting point, must backfire. For example, the attempt of a socialist society to induce work by the offer of prestige, rather than material incentives, not only cannot succeed, but must bring the opposite of prestige to those who would be willing to work for it. To mine coal, drive a truck, harvest a field, work in a factory—to do virtually any of the run-of-the-mill jobs that occupy the bulk of the labor force—for the sake of prestige, would be to mark a person as nothing but a fool. He would have to be a fool to drive himself day in and day out, sweating and straining, all for the sake of nothing more than, in effect, being called a good boy.

The objective superiority of the goods of modern capitalism is not called into question by the fact that in our culture many people want to own such goods as horses, canoes, bows and arrows, and so on, and in some cases prefer units of these goods to units of more advanced goods serving the same needs. Such choices do not by any means necessarily mark these people as primitivists. There are conditions in which the horse is superior to the automobile—for example, where there are no roads. Similarly, canoes can navigate shallow waters that a motorized craft cannot. Also, the physical experience that a horse or canoe affords is different from

that provided by an automobile or motorboat: they enable one to observe things more closely and more leisurely, for example.

The desire to own such goods, even though one lives in the conditions of modern civilization, is actually nothing more than a manifestation of our limitless need for wealth: a person wants one or more automobiles as his normal means of transportation, and a horse as a further refinement, as it were, of his ability to locomote. Thus, he loads his horse into a horse trailer, hitches it to his car, or, better, motor home, and drives to the edge of terrain where only horses can go. Or he simply goes for a ride on a nearby trail to experience the motion of a gallop and the wind on his face. To be able to enjoy the widest possible range of pleasurable and beneficial experiences is precisely why an individual desires to obtain the greatest possible amount of wealth. But to obtain it, and have the time to enjoy it, he must be able to accomplish everything that is not itself pleasure, or otherwise valued for its own sake, in the shortest possible time. If, for example, what a person wants is the experience of leisurely riding along a beautiful mountain stream, then he doesn't want to waste that time using a horse to cross the country to get to the mountains. For that, he wants a motor vehicle. It (together with roads) is objectively superior to the horse as a normal means of transportation. As a direct source of enjoyment, however, there is still a need for horses, even in the conditions of a modern economy. In effect, the limitless need for wealth embraces a kind of recapitulation of the goods that were prominent in less advanced conditions.

The Objective Value of a Division-of-Labor, Capitalist Society

I have shown that economic progress is not a matter of arbitrary preference, but is objectively desirable—desirable on the basis of our nature as rational beings. The goods that result are objectively improvements, and the process of acquiring them—the continuous thinking that must be done—is called for by our nature as rational beings.

The objective value of economic progress implies that the cultural values that make economic progress possible are likewise objectively better than those that stand in its way. These values, of course, are the values that underlie the division of labor and capitalism—above all, reason, science, technology, individual rights, limited government and economic freedom, and private ownership of the means of production. In the name of being able to see, hear, move, or do anything that our senses, limbs, and minds enable us to do—in short, in the name of being able to live as human beings—these values deserve to be upheld.

Indeed, the same principle that establishes the objectivity of the economic advances of modern capitalism directly establishes the objectivity of the superiority of modern capitalist civilization as such, in comparison to any other form of civilization. Here the attribute that serves as the standard is the ability to acquire and apply knowledge. Modern capitalist civilization—modern “Western” civilization—possesses this ability in greater measure than any previous civilization. In addition to knowledge of the laws of logic and the principle of causality, which were known to the Greeks and Romans and which enabled them to surpass all previous civilizations in the ability to acquire knowledge, modern Western civilization possesses not only a much more highly developed knowledge of the laws of mathematics and science but also a division-of-labor economy and, above all in its Anglo-Saxon variant, the freedoms of speech and press. As I will show in Chapter 4, a division-of-labor economy makes possible an enormous and progressive increase in the amount of knowledge that a society possesses and in the application of knowledge to production. The freedoms of speech and press also play an essential role in the increase in knowledge by guaranteeing the individual's right to disseminate knowledge without being stopped by the coercive power of the state operating in support of the ignorance, fears, or superstitions of any individual or group. Thus, capitalist civilization deserves to be upheld in the name of the value of knowledge.

It should go without saying that capitalist civilization is open to men of all races, as the brilliant success of Japan and several other Oriental nations dramatically illustrates. It is not the civilization of the white man, but of all men who wish to prosper and are prepared to adopt reason as their fundamental means of doing so. Those who view it, whether with pride or with hatred, as the civilization of the white man only, are implicitly racists, in that they view civilization and culture as being racially determined. The fact is, of course, that civilization and culture, above all, modern capitalist civilization, is a body of knowledge and values that is accessible to all of mankind.¹⁷

While extolling the values of capitalism, it must be stressed that nothing that has been said or that will be said in this book should be taken to imply a belief on my part that contemporary Western or American culture is perfect. Far from it. Obviously some very serious flaws mar our culture. And they have been growing.

Our culture's basic flaw is its philosophic contradictions.¹⁸ These contradictions, in the form of irrationalist doctrines, such as that of cultural relativism, lead it to attack its virtues. Thus, we witness the spectacle of our culture flagellating itself for its successes in science,

technology, and the creation of wealth. We see the spectacle of its intellectuals holding the most primitive and barbaric cultures as superior to their own, as they declare that all cultures are of equal value except their own, which is to be despised.

The spectacle is particularly gross in regard to the culture of the United States, which is the foremost capitalist country. The United States is denounced by its enemies as the leader of the evil, reactionary forces—the champion of monopoly capital and imperialism. Many of its own intellectuals join the denunciations and find nothing but evil in the history of their country and in its current policies. Yet all the flaws of the United States were flaws of being inconsistent with its own magnificent principles. Its flaw today, which is potentially deadly, is that many of its intellectual leaders have been corrupted to the point of despising those principles, above all, the principles of limited government and economic freedom, and, more recently, the values of science and technology, as well.

4. The Law of Diminishing Marginal Utility and the Limitless Need for Wealth

The principle that man's desire for wealth is limitless is fully consistent with the law of diminishing marginal utility, one of the most important and well-known principles of economics. The law of diminishing marginal utility states that *the utility or, equivalently, the importance or personal value that an individual attaches to a unit of any good diminishes as the quantity of the good in his possession increases.*

An example drawn from Böhm-Bawerk, the leading theorist of marginal utility, will illustrate the principle. Imagine that an isolated frontiersman, say, of the old American West, requires five sacks of grain, which must last him until his next harvest. He needs one sack to meet his minimum need for nutrition. Without it, he would die of starvation. He needs a second sack to be sure of having enough food to keep up his health and strength. A third sack enables him to raise some poultry and satisfy his hunger completely. With a fourth sack he can distill some brandy. With a fifth sack he can feed some parrots, from which he derives amusement.

If our frontiersman in fact possesses only one sack of grain, he will value it as highly as his very life. This is because, in this context, the possession of a sack of grain is a necessary condition of his survival; if he loses his one and only sack of grain, he will die. If, however, he possesses two sacks of grain, he will not value one sack as highly as his life, but only as highly as the maintenance of his health and strength. Because now, in this context, this is what depends on the possession of a sack of grain;

if he lost one of his two sacks, it would be his health and strength, not his life, that would be threatened. In the same way, if he should possess three sacks of grain, he will value one sack only as highly as the remaining satisfaction of his hunger. With the possession of a fourth sack, the value he attaches to any one sack falls to the importance he attaches to having brandy; with a fifth sack, it falls to the importance he attaches to feeding the parrots. Thus, the marginal utility of a good can be thought of as the utility of the last unit of a supply, giving all due allowance to the more important want satisfactions provided by the earlier units of the supply, and thus falling as the number of such earlier units increases.¹⁹

The law of diminishing marginal utility rests on two closely related foundations. First, because goods have the power to satisfy wants, successive units of a good that are used to satisfy a want necessarily encounter wants that are more and more satisfied. For example, if I am very thirsty, the first glass of water I drink meets a very intense need. But that glass of water helps to satisfy the need. The second glass of water I drink, therefore, goes to serve a need that is less urgent precisely because it is already partly satisfied by virtue of the first glass of water. The same, of course, is true of the frontiersman's grain, insofar as he consumes it.

The second foundation of the law of diminishing marginal utility is that insofar as we must choose which of our wants to satisfy, and act rationally in doing so, we choose to satisfy our more important wants in preference to our less important wants. Our frontiersman, for example, chooses to feed himself ahead of the parrots. Indeed, as far as we are able, we devote our goods to the satisfaction of the most important of our wants that they are capable of satisfying. Diminishing marginal utility follows from this because, with the units of the initial supply devoted to serving the most important of the wants they can serve, the only wants that remain to be served by an addition to the supply are necessarily wants that are less important than those already being served.

The concept "most important of our wants that a good is capable of satisfying" must be understood as *a variable range*, whose extent depends on the quantity of the good we possess. Our frontiersman, for example, devotes his supply of grain to its most important uses even when he feeds parrots. In the context of possessing five sacks of grain, feeding parrots is the most important use to which he can devote his *fifth* sack. While it is certainly not as important as devoting any of his first three sacks of grain to feeding himself, it is certainly more important than devoting a fourth sack of grain to feeding himself (which might be unhealthy and make him feel ill) and more important than any other use to which he can devote that fifth sack, given the existence of the other four.

We satisfy our most important wants in descending order of importance. The larger the number of units of a good at our disposal, the further down in the scale of importance we are able to carry the satisfaction of our wants. The marginal unit of a supply is devoted to the most important wants that it can serve, but these wants are necessarily less important than the wants being served by the “earlier” units of the supply. The marginal wants that a good serves should be thought of not as being unimportant, *but as being the least important of the most important wants that its supply suffices to serve*. The marginal wants are always *more important* than any of the *submarginal* wants, that is, wants whose satisfaction would require a still larger supply of the good.

It should be realized, of course, that the utility of the marginal unit of a supply determines the utility of *any* of the units of that supply at that moment. If, for example, our frontiersman were to attach a tag to one of his five sacks of grain, and label it specifically as the sack necessary to his survival, the utility of that particular sack would still be no greater than the utility of a sack specifically labeled as necessary to the feeding of his parrots. This is because irrespective of any such labeling, it is still only a question of one sack out of a supply of five. If the particular sack labeled necessary to survival were lost, the sack previously designated as reserved for the feeding of the parrots could take its place. By virtue of making this substitution, the actual loss would fall on feeding of the parrots, and that utility, therefore, would be the marginal utility of the sack in question.

As previously stated, the law of diminishing marginal utility is perfectly consistent with the fact that man’s need for wealth is limitless. It is necessary to stress this point in view of the misconception spread by Galbraith that increasing wealth, and the consequent fall in the marginal utility of a unit of wealth, makes the pursuit of wealth progressively less important.²⁰

One reason for the consistency between the law of diminishing marginal utility and the limitless need for wealth is the elementary fact that the *total utility* of a person’s supply of wealth must go on increasing so long as wealth has any positive marginal utility to him whatever. For example, the fact that the fifth sack of grain has a lower marginal utility to the frontiersman than the fourth does not contradict the fact that five sacks of grain have a greater total utility to him than four and thus that it is better for him to own five sacks than four. So long as additional wealth has any marginal utility whatever, there is a need for more wealth.

Of course, if one considers a very narrow type of good, such as bread, say, it is possible to imagine additional units beyond a point being of negative utility, and, therefore, a larger supply being of less utility than a smaller

supply. This would be the case, for example, if the additional units either had to be eaten by people who already had all they wanted or else would simply rot and impose costs of removal and cleanup. But, for reasons explained earlier in this section, it could certainly never be the case that all or most goods, or, therefore, wealth in general, could fall into this category.

Furthermore, it should be realized that the very process of increasing the amount of wealth that is available to the average member of any society entails the opening up of *new uses for additional wealth*, which has the effect of increasing the marginal utility of additional units of wealth. The opening up of new uses for wealth occurs because essential to the ability to increase the supply of wealth is scientific and technological progress, which makes possible not only improved methods of producing goods of the kind that already exist, but also brand new kinds of goods. Thus, for example, the invention of the electric motor and the internal combustion engine, which radically increased our ability to produce and enjoy wealth, did not result in our sating ourselves with a vastly increased production of such goods as candles and ox-carts. On the contrary, as part of the same process of improvement, these inventions were accompanied by the invention of the electric light and all the electrical appliances and, of course, the automobile. In this way, increases in the ability to produce raise the marginal utility of additional wealth along with providing it.

Thus, an automobile represents perhaps a hundred or a thousand times the wealth represented by an oxcart, and, at the same time, is probably of correspondingly greater marginal utility than an oxcart. Certainly, the marginal utility of a second automobile does not represent a drop in the marginal utility of wealth to the point that would correspond to the possession of a second hundred or thousand ox-carts. Along the same lines, one might think of a two-hundred horsepower automobile as representing the material equivalent of two hundred horses. Wealth representing a two-hundredth part of an automobile has a higher marginal utility to the owner of an automobile than would the wealth representing a two-hundredth horse. Thus, the effect of a growing ability to produce is not only more wealth, but also a higher marginal utility of the additional wealth in comparison with what it would otherwise have been (if somehow the additional wealth had been able to come into existence without such technological advances). And, as these examples imply, the effect of a growing ability to produce is a tendency toward an increase in the size of the marginal unit of wealth, as well.

This last point requires elaboration. The size of the marginal unit is never something fixed and immutable. It is always a matter of context, and the context is always

the circumstances and conditions with which the individual is confronted. If, for example, our frontiersman had two of his five sacks of grain stored in the same place, and that place was threatened by a fire, what would be at stake for him would be the importance of satisfying the wants dependent on the two sacks together. The two sacks together would have to be evaluated, and they together would constitute the marginal unit. As von Mises once said in a discussion with the present author, the marginal unit is whatever is the amount under consideration.

As people grow richer, the size of the marginal unit tends to increase. Not only do they deal with things like automobiles instead of oxcarts, but richer people deal with Cadillac- or Mercedes-level automobiles rather than Chevrolet- or Toyota-level automobiles. When differences in quality are considered, a house, a suit or a dress, a restaurant meal, practically everything, tends to be a larger-sized unit of wealth for a richer person than for a poorer person. When this is taken into account, it becomes clear that it is a great mistake to assume that as wealth increases, the utility of *the marginal units actually dealt with* diminishes. On the contrary, the utility of these units actually increases! Unit for unit, a Cadillac has a higher marginal utility than a Chevrolet; a large, luxurious house has a higher marginal utility than a small, modest house; and so on.

Furthermore, the fact that the utility of a marginal unit of wealth of given size diminishes as the quantity of wealth available to us increases is actually an important aspect of the desirability of increasing our wealth. What we rationally want is to be in a position in which the marginal utility of a unit of wealth of any given size more and more approaches zero, while what we deal with more and more is progressively larger-sized units of wealth. We want to be in a position in which the loss of the wealth represented by \$10, say, is absolutely unimportant to us; better still, in which the loss of the wealth represented by \$100, \$1,000, or \$10,000 is absolutely unimportant to us. The loss of wealth represented by \$10 will be unimportant to us when we are rich enough to afford spending \$50 or \$100 for a single fine meal rather than \$10 for a whole day's food—when, in other words, \$50 or \$100 replaces \$10 as the representative of a marginal unit of food. The loss of \$1,000 will be unimportant to us when we can afford to spend \$50,000 for a second automobile, perhaps, rather than just \$1,000 for our one and only ancient used car. The loss of \$10,000 will be unimportant to us when we can afford to spend \$1,000,000 for our second or third home rather than just \$10,000 for our one and only small used trailer.

Thus, we rationally want more wealth in order to be able to deal with marginal units of wealth of progres-

sively larger size, and to be less and less concerned with units of wealth of any given size. In the spirit of the welcoming party allegedly once given by American millionaires to the famous nineteenth-century English defender of capitalism Herbert Spencer, the symbolic ideal is to be able to afford to use hundred-dollar bills to light one's cigar—while dealing with mansions, yachts, and private railway cars as the significant marginal units of one's life.

5. Applications of the Law of Diminishing Marginal Utility

The law of diminishing marginal utility has important applications. It is appropriate to consider several of them here, both because they shed light on the rationality of economic activity and because, in one case at least, they provide positive confirmation of the fact that man's need for wealth is limitless.

Resolution of the Value Paradox

As explained in the Introduction, the law of diminishing marginal utility makes possible a resolution of the classical economists' paradox of value—the seeming paradox constituted by the fact that goods of apparently the lowest utility, such as diamonds, are normally more valuable in exchange than goods of apparently the highest utility, such as water. This apparent paradox was, of course what prevented the classical economists from being able to ground their theory of exchange value and prices in utility.

When people regard water as more useful than diamonds, what they have in mind is that if one had to choose between having no water or no diamonds, one would obviously choose to have no diamonds. Up to a considerable point, units of water are vastly more important than units of diamonds. But because of the operation of the law of diminishing marginal utility, a point is reached at which the utility of the *marginal* unit of water falls below the utility of the *marginal* unit of diamonds. The first gallon of water, the hundred and first, or probably even the thousand and first gallon of water, is more important than the first carat of diamonds or even the first ten or a hundred carats of diamonds taken together. But at some point, after one has all the water necessary for drinking, cooking, washing, irrigating, and so forth, the marginal utility of water falls below the marginal utility of diamonds. The extremity of the abundance with which nature provides water and the extremity of the scarcity with which it provides diamonds jointly operate to establish a far higher *marginal* utility of diamonds than of water in normal circumstances.

Thus the fact that in the normal circumstances of

civilized life people value diamonds above water is not at all paradoxical or irrational. It is perfectly consistent with considerations of genuine utility, provided the latter are properly understood—that is, in the light of the principle of diminishing marginal utility.

By the same token, the fact that people nowadays desire to possess such things as power windows on their automobiles, and are willing to pay substantial sums for what many may regard as relatively modest improvements in fashion or style, is also perfectly consistent with rational principles of behavior. It is a question of the context of how much wealth or income one has available and thus of the marginal utility to the individual of a unit of wealth or income. If one has sufficient wealth or income so that one is already able to provide for a very full satisfaction of such needs as those for food, clothing, and shelter, then, indeed, the most important use for the price of power windows or the price of a relatively modest improvement in fashion or style may well be the purchase of the power windows or the improvement in fashion or style. One must always consider what the individual's choices are in the context confronting him. If the choice is, for example, the power windows or an improvement in his hi-fi equipment, because all wants of greater importance are already provided for, then the purchase of the power windows may very well be the most important use for the money in question.

Determination of Value by Cost of Production

The law of diminishing marginal utility also makes it possible for the first time to understand the actual role of cost of production in the determination of prices. Although the classical economists mistakenly believed that cost of production provided an explanation of prices that was a logical alternative to an explanation on the basis of utility, an understanding of marginal utility makes it possible to grasp the determination of price by cost as a major instance of the operation of the law of diminishing marginal utility.

As Böhm-Bawerk and Wieser explained, there are numerous cases in which cost of production is in fact the immediate determinant of the price of a good. These are cases in which a good of relatively high direct marginal utility is produced by factors of production whose supply is abundant enough to permit their employment in the production of other goods of relatively low marginal utility. In such cases, *the marginal utility of the factors of production is determined by the utility of the least valuable of the products for whose production their supply is sufficient*. The value of the factors of production, determined in this way, then reduces the value of the products of higher direct marginal utility to the utility of their least valued product. Thus, cases in which prices

are determined by cost of production actually represent a special application of the law of diminishing marginal utility. Namely, the value of all the products of the same factors of production, however high their own, direct marginal utility, is reduced to the marginal utility and value of the marginal product of those factors of production.²¹

Böhm-Bawerk's example of the frontiersman with five sacks of grain, originally used to illustrate the principle of diminishing marginal utility itself can serve, in a slightly modified form, to illustrate the present point. Thus, instead of imagining a sack of grain labeled "sack required for survival," let us imagine a quantity of biscuits, baked from flour made from this sack of grain, and labeled "biscuits required for survival." As before, the frontiersman possesses four additional sacks of grain, which are sufficient for satisfying his needs down to the point of feeding parrots. If now this supply of biscuits is destroyed, the frontiersman's life is not threatened any more than it was before, when his sack of grain labeled sack required for survival was lost.

Just as he could previously replace that sack of grain, so now he can replace the biscuits by withdrawing grain from the feeding of parrots. Thus, even though the direct marginal utility of the biscuits, like the sack of grain before them, is as high as that of his life itself, the ability to replace them, by withdrawing supplies from the feeding of parrots, reduces their actual, effective marginal utility to the much lesser marginal utility of feeding the parrots.

What is present here is that the value of the biscuits is reduced to the value of the grain which makes possible their replacement, and which in turn is determined by its marginal utility. Thus, the value of the biscuits, like the value of the sack of grain before it, labeled sack required for survival, comes to be determined by marginal utility at a point corresponding to the much lesser importance of feeding parrots. In this way, determination of the value of a product on the basis of the lesser value of the means required for producing it, represents the operation of the principle of marginal utility.

Determination of Consumer Spending Patterns

In addition, and very important, the law of diminishing marginal utility helps to explain the pattern of demand that prevails in the economic system at any given set of prices of goods. People can buy goods in many different combinations. They can buy more of some goods by curtailing their purchases of other goods. The law of diminishing marginal utility implies, however, that as people increase their purchases of any good, successive additional units of it are accompanied by diminishing marginal utility. By the same token, as they

restrict their purchase of other goods, to make additional funds available for the purchase of this particular good, the remaining units they purchase of these other goods acquire greater marginal utility.

From these facts, a principle of equilibrium in spending patterns emerges, which is that beyond a point, additional units of any good are not purchased at the expense of further reductions in the purchase of other goods because the marginal utility gained would be less than the alternative marginal utility forgone. Purchases in every line are carried only to the point at which the marginal utility derived is greater than the alternative marginal utility that could be derived by devoting the price of the good to the purchase of other goods. The equilibrium that emerges is defined by the condition that the marginal utility of each good purchased in each line is greater than the marginal utility of any other good or combination of goods that could alternatively be purchased with its price in any other line. At the same time, the marginal utility of an additional unit in any line is less than the marginal utility that would have to be forgone in other lines to make possible its purchase.

For example, consumers carry their purchases of food, clothing, shelter, and entertainment only up to the point at which the marginal utility of a unit of each of these goods exceeds the marginal utility of any alternative good or combination of goods that they might purchase with the same money. They limit their purchases in each line at the point at which the marginal utility gained by the purchase of an additional unit would be at the expense of a greater loss in marginal utility by virtue of having to restrict unduly the purchase of one or more other such goods. People wish to achieve a certain balance in the different areas of their consumption. Normally, they do not want to live in penthouses if it means having to eat beans and wear rags. Nor, by the same token, do they usually want to drink champagne and eat caviar if that means having to live in a hovel. They tend to achieve an equilibrium that is characterized by the utility of the last units purchased in each line being greater than the utility of any additional units that might be purchased in other lines.

In an overzealousness for the use of mathematics, economics textbooks often describe the equilibrium of spending patterns by claiming that the marginal utility of each good comes to stand in a uniform proportion to its price. Thus, it is said, the

$$\frac{\text{Marginal Utility of Good A}}{\text{Price of Good A}} = \frac{\text{Marginal Utility of Good B}}{\text{Price of Good B}}$$

and so on for all goods and all prices. It is claimed that this mathematical equilibrium results from the fact that

wherever the equal proportionality of marginal utility to price does not exist, it pays to spend less for the goods of relatively lower marginal utility and more for the goods of relatively higher marginal utility, which raises the marginal utility of the former category and reduces that of the latter category relative to their respective prices until equal proportionality does prevail.²²

What the use of the above mathematical formula overlooks is the fact that marginal utility often undergoes major discontinuities. For example, the marginal utility of a steering wheel in an automobile relative to the price of the steering wheel is enormous, for it is as great as the marginal utility of the entire automobile. On the other hand, the marginal utility of a mere second headlight on the automobile relative to its price is comparatively quite modest. In such circumstances, the above described mathematical doctrine implies that one should forgo the purchase of the second headlight in order to purchase a second steering wheel. This, of course, is obviously nonsensical. Equilibrium in such cases cannot be described in terms of a uniform proportionality of price to marginal utility, but only in terms of the utility of the last units purchased in any line being greater than that of any alternative additional units that might be purchased with the same money in other lines. In effect, the condition of equilibrium is that the marginal utility of good A exceeds the utility of any additional units of goods B, C, etc., which might be purchased with its price, while, at the same time, the marginal utility of good B exceeds the utility of any additional units of goods A, C, etc., which might be purchased with its price, and so on for all goods.

Say's Law

Finally, and what is most relevant to the fact that the need for wealth is limitless, the principle of diminishing marginal utility helps to explain the phenomenon of partial, relative overproduction and underproduction described by Say's Law. It thus helps to explain why any alleged general or absolute overproduction, with the supply of wealth allegedly surpassing man's need for wealth, is never actually present.²³ In so doing, it provides important confirmation of the fact that man's need for wealth has no practical limit.

To understand this point, it must be realized that increases in the ability to produce always take place in particular industries. Very often, devoting the whole or even the greater part of such increased ability to produce to an expanded production of the particular products of those industries would result in the marginal utility of the products in question falling below the marginal utility of additional quantities of other products. These other products are products whose supply could be increased by a withdrawal of capital and labor from the industries in

which the improvements in the ability to produce have taken place. To the extent that the increased ability to produce is unduly concentrated in the particular industries in which it originates, the products of such industries may be said to be in a state of partial and relative overproduction, while the products of other industries are in a corresponding state of partial and relative underproduction.

For example, devoting a doubled ability to produce potatoes with the same labor to an actual doubling of the supply of potatoes, would result in a partial and relative overproduction of potatoes. At the same time, there would be an equivalent partial and relative underproduction of other goods, additional quantities of which possess a higher marginal utility than the additional potatoes and which could be produced with capital and labor used to produce the additional potatoes. The problem in such a case is not any actually excessive ability to produce, but merely the misapplication of an increased ability to produce in an undue concentration on the production of a particular good. The solution is thus simply a better balance in the production of additional goods.²⁴

Further major applications of the law of diminishing marginal utility will be developed in Chapter 5, in connection with the discussions of the concept of demand and of price determination.

6. "Scarcity" and the Transformation of Its Nature Under Capitalism

Man's limitless need for wealth, combined with the respective natures of desires and goods, is responsible for the fact that the desire to consume always far outstrips the ability to produce. Desires are mental phenomena, based on thoughts and concepts. Goods are physical phenomena, requiring for their existence the performance of human labor. For all practical purposes, the referents of concepts are limitless; and to desire, one need do hardly more than imagine. But goods are always specific concretes, and each must be produced, requiring labor and effort. In essence, our desires outstrip our ability to produce by virtue of the limitless range of the mental in comparison with the physical and thus by virtue of the fact that the range of our imaginations is always incomparably greater than the power of our arms.

This relationship remains true no matter how much we may augment the power of our arms by means of tools and machinery. For at the same time, as part of the same process, we augment the power of our imaginations, in that the new knowledge required to provide the tools and machines also opens up new vistas in terms of what can be produced. For example, as already mentioned, the invention of the electric motor and the internal combus-

tion engine did not result in our satiating ourselves with a vastly increased production of candles and oxcarts, but, as part of the same process of improvement, was accompanied by the invention of the electric light and all the electrical appliances and by the invention of the automobile. Thus, the desire for goods grew with the ability to produce them. It will continue to grow with further improvements in the ability to produce. If, to take an extreme example, the day should ever come when radical advances in technology make it physically possible for us to be satiated with things like automobiles, the same radical advances in technology will open up the possibility of producing things like rocketships accessible to the general public and vacation homes on the moon. Thus, the desire for goods will always remain far greater than the ability to produce them.

Economists almost universally describe the condition in which the desire for wealth exceeds the amount of wealth available as one of "scarcity." Scarcity, they hold, means any limitation of wealth relative to the need or desire for wealth, irrespective of whether the limitation proceeds from the lack of wealth or the abundance of desires.

If one wishes to retain this terminology, one must say that capitalism radically transforms the nature of scarcity. For the people of precapitalistic societies, scarcity means a deficiency of wealth relative to urgent biological needs; it means supplies of food insufficient to still hunger; supplies of shelter and clothing insufficient to provide protection from the elements. Under capitalism, on the other hand, scarcity does not mean any such deficiency of wealth, but a vast and growing supply of wealth that lags behind the *desire* for wealth—a desire that always exceeds it, always grows as it grows, and that provides the impetus for its further growth. Scarcity under capitalism actually means economic ambitiousness, and is the cause of the progressive elimination of scarcity in the urgent biological sense.

For example, under capitalism, the scarcity of food quickly ceases to mean starvation. Instead it is a situation in which grain supplies have become abundant, but the point has not yet been reached where people can have all the meat they want. And then it ceases to mean even a deficiency of meat, but the fact that not enough of the meat supply is in the form of sirloin steak, and so on. Similarly, a scarcity of housing quickly comes to mean not a scarcity of dwelling space as such, but only a scarcity of ever more improved, more solidly constructed, and more luxurious dwelling space.

At each stage, the desire to advance to a higher stage makes the threat to urgent biological needs more remote. In a country in which the scarcity of food is merely a scarcity of meat, a year of bad crops does not threaten

famine. It just means that less grain will be devoted to feeding meat animals, and people will end up with less meat. In a country in which the scarcity of food means a scarcity of sirloin steak, a year of bad crops means merely that people will have to switch to somewhat poorer cuts of meat, as they utilize a smaller but still abundant supply of meat animals more fully for human consumption. And as a general principle, cutting across all branches of production, the growing abundance of supplies in a capitalist society steadily prolongs and enriches human life at the same time that it further and further removes such direct threats to human life as famine and plague. Evidence for the truth of this proposition can be found in the fact that hardly anyone dies from hurricanes, tornadoes, volcanoes, earthquakes, or contagious diseases in the United States, while large numbers do so in the poor and backward countries. Our better record is the result of our greater progress in wealth—in the form of such things as better constructed buildings, better means of transportation, and better medical facilities, as well as a more abundant and varied food supply.²⁵ There is no fixed limit to the process by which the increasing production of wealth can further enhance and extend human life and its enjoyment.²⁶

7. Time Preference and the Scarcity of Capital

In addition to the law of diminishing marginal utility, there is a second major economic principle of valuation that closely bears on the subject of scarcity, namely, that of time preference. Time preference operates to maintain the specific scarcity of savings and capital.²⁷

According to the principle of time preference, an individual values goods available to him in the present more highly than goods available to him in the future, and goods available to him in the nearer future more highly than goods available to him in the more remote future. For example, he values having a house, a car, or a television set now, more highly than having it a year from now, and more highly having it a year from now than two years from now.

The principle of time preference holds that the prospective location of goods in time has a similar effect on our valuation of them as the location of things in space has on our visual perception of them. The further away from us things are in space, the smaller do they appear to us in our field of vision. The temporally more remote goods are in our field of valuation, so to speak, the smaller is the value we attach to them.²⁸

Like any principle, that of time preference must be understood as applying other things being equal. For example, I would probably prefer to have a bathing suit in July rather than in January, even though July may lie

further in the future than January. In this case, other things are not equal. Much more benefit can be obtained from a bathing suit in the heat of July than in the cold of January. The appropriate application of the principle of time preference in this case is the fact that if I want to go swimming, I value the possession of a bathing suit for this coming July more highly than for the following July.

Similarly, the prospective marginal utility of a unit of a good in the future can be higher than its marginal utility in the present, if one expects to have fewer units in the future. For example, instead of eating two sandwiches now, a person can very well save one for later, because the marginal utility of a first sandwich later is greater than the marginal utility of a second sandwich now. Here the appropriate application of the principle of time preference is that a person attaches greater importance to consuming his first unit of a good today than to consuming his *first* unit tomorrow, and to consuming his second unit today than to consuming his *second* unit tomorrow. The fact that future units in a less abundant supply can have a greater marginal utility than present units in a more abundant supply does not contradict the principle of time preference, since that principle refers to the valuation of present and future units of equal supplies.

Finally, the principle of time preference is not contradicted by the fact that the prices of commodity futures are usually higher than the prices of the corresponding “cash” commodities available for immediate delivery. For example, in the month of September, the price of corn for delivery in December is always higher than the price of corn for immediate delivery, while the price of corn for delivery in the following March is still higher than that for delivery in December. Such a price structure does not mean that, other things being equal, people prefer commodities in the future to commodities in the present. On the contrary, month by month they are consuming the stocks of commodities, demonstrating that they prefer present consumption to future consumption. The ascending price structure of commodity futures is the reflection of the prospectively increasing scarcity of commodities between harvests, and/or of the need to compensate those who store supplies of commodities for future sale for the costs they incur in so doing and for tying up their capital in such investments. In the absence of such an ascending price structure, time preference would result in the unduly rapid consumption of stocks of commodities.

The Foundations of Time Preference

Time preference is implied in the very nature of valuation, and, indeed, of human life itself. All other things being equal, to want something is to want it sooner rather than later. If all other things are equal in two succeeding periods of time and a good exists which could be con-

sumed in either period, then the very fact of the good's being valued implies that it must be consumed in the first period. If it is not consumed in the first period, then the identity of conditions implies that it also cannot be consumed in the second period. Hence, the good simply would not be consumed and, by implication, its consumption would be demonstrated not to be valued. If, however, the good is consumed in the first period, its nonconsumption in the second period does not contradict its being wanted just as much in the second period; it is simply unavailable in the second period.

The nature of human life implies time preference, because life cannot be interrupted. To be alive two years from now, one must be alive one year from now. To be alive tomorrow, one must be alive today. Whatever value or importance one attaches to being alive in the future, one must attach to being alive in the present, because being alive in the present is the indispensable precondition to being alive in the future. The value of life in the present thus carries with it whatever value one attaches to life in the future, of which it is the precondition, *plus* whatever value one attaches to life in the present for its own sake. In the nature of being alive, it is thus more important to be alive now than at any other, succeeding time, and more important to be alive in each moment of the nearer future than in each moment of the more remote future. If, for example, a person can project being alive for the next thirty years, say, then the value he attaches to being alive in the coming year carries with it whatever value he attaches to being alive in the following twenty-nine years, plus whatever value he attaches to being alive in the coming year for its own sake. This is necessarily a greater value than he attaches to being alive in the year starting next year. Similarly, the value he attaches to being alive from next year on is greater than the value he attaches to being alive starting two years from now, for it subsumes the latter value and represents that of an additional year besides.

The greater importance of life in the nearer future is what underlies the greater importance of goods in the nearer future and the perspective-like diminution in the value we attach to goods available in successively more remote periods of the future.

The Scarcity of Capital

Later discussion will show that time preference has an important bearing on the determination of the rate of profit and interest.²⁹ What must be stressed here is that time preference prevents the existence of profit and interest from always resulting in saving and the accumulation of additional capital. For example, assuming a constant buying power of money, if the rate of profit and interest is 5 percent, the implication is that by saving and

investing \$100 this year, one can have and consume \$105 worth of goods next year. The reason that people do not all rush to save as much as possible, despite the fact that doing so would enable them to consume more in the future, is that they have time preference. Time preference results in people preferring an additional \$100 of consumption today to an additional \$105 (or whatever the figure may be) of consumption a year from now. It thus acts to limit the extent of saving and capital accumulation and to contribute to the scarcity of capital.

Time preference manifests itself in the extent to which individuals make provision for the future relative to their current consumption. An individual with an extremely high time preference will have no savings. He will consume his entire income and not use any of it to provide for his future consumption. By the same token, an individual with a very low time preference will seek to accumulate savings to a substantial multiple of his current income and consumption.

There are two dimensions to the scarcity of capital and capital goods. In one respect, capital goods are simply as scarce as our labor and ability to produce consumers' goods. To whatever extent our desire for consumers' goods, such as houses and cars, exceeds our ability to produce them, our implicit, indirect desire for things like bricks and lumber, steel sheet and tires, and the appropriate kinds of equipment used in making houses and cars, exceeds our ability to produce them. This kind of scarcity can be thought of as a horizontal scarcity of capital, in the sense that as wide as is our desire for consumers' goods relative to our ability to produce them, equally wide is our desire for the corresponding capital goods relative to our ability to produce them. Such scarcity of capital is obviously as ineradicable as the scarcity of wealth.

The second dimension of the scarcity of capital refers to the fact that goods can be produced with varying amounts of capital per unit, that is, with varying degrees of *capital intensiveness*. For example, a railroad can be constructed to go from point A to point B directly, or with various detours to avoid obstacles like lakes and mountains in between. Usually, constructing the bridges and tunnels required for the more direct route requires a greater capital investment than the longer, indirect route. In deciding which route to adopt, a railroad company must weigh the disadvantage of the larger capital investment required against the advantage of lower fuel and labor costs and reduced wear and tear on equipment in every year thereafter.

The choice of whether to employ more or less machinery in a manufacturing process is of the same nature: one must weigh the disadvantage of a larger initial outlay for the machinery against the advantage of lower labor

costs in each year of the machinery's use. Whether or not it pays to improve a piece of farmland through irrigation or drainage, or to improve a mine by widening or deepening its shafts, is also similar in nature.

The extent to which our products are aged, as in the case of whiskey, beef, and woods of different growing time, is also a matter of differences in the amount of capital employed per unit of output. For example, in order for the whiskey companies to turn out a unit of eight-year-old scotch every year, they need to have capital representing units of scotch of each of eight different years of age on hand in the pipeline, so to speak. In order to turn out the same quantity of twelve-year-old scotch each year, they need correspondingly more capital—more units of partially aged scotch for every one that is fully aged. In the same way, lumber companies harvesting trees with a twenty-five-year growth cycle need growing stands of trees representing years one through twenty-four for every stand of trees they harvest today, and lumber companies harvesting trees with a fifty-year growth cycle need a correspondingly larger number of stands of trees at various stages of growth for every one they harvest today.

A similar principle applies to the use of more valuable materials in preference to less valuable materials. Any use of more valuable materials at any given stage of production is likely to reflect the performance of correspondingly more labor, or more skilled labor, prior to that stage of production, and thus a higher degree of capital intensiveness. Thus, for example, a house made of bricks requires the use of more capital than a house made of wood, insofar as more previously performed labor is required to produce bricks for a house of a given size than lumber for a house of the same size. The same applies to the extent to which products contain various previously produced components and accessories. For example, other things being equal, an automobile with automatic transmission, an air conditioner, power windows, and the like, requires a larger quantity of capital in its production than one without these things or equipped with fewer of them.

Different industries have very different degrees of capital intensiveness. A far larger amount of capital investment stands behind the average dollar that is received in the form of house rent or a mortgage payment than stands behind the average dollar received as payment for restaurant meals or haircuts. Similarly, it takes more capital investment to earn a dollar of sales in the electric utility industry than it does in the motion picture business, and more in the motion picture business than it does in the grocery business.

The extent to which capital is scarce in this second sense—in what we can call its vertical dimension—is determined by time preference. In a society characterized

by relatively low time preference—that is, by a willingness to forgo present consumption to the point of making substantial provision for the future—the methods of production will tend to be relatively capital intensive: relatively capital-intensive industries, such as railroads and electric utilities, can exist, and will be larger in relation to less capital intensive industries; the railroads will be more able to build bridges and tunnels, and the factories to adopt labor-saving machinery; the farms and mines will be more improved; a wide variety of products will enjoy the benefit of the use of better-quality materials and of greater aging.

Our discussion of the causes of capital accumulation, later in this book, will show how the lower is the degree of time preference in a society, and thus the greater is its overall degree of capital intensiveness, the greater is its ability to adopt technological advances and to enjoy a cumulative process of capital accumulation.³⁰ What must be emphasized here, however, is that the existence of time preference prevents the scarcity of capital in its vertical dimension from ever being overcome.

Before the scarcity of capital in its vertical dimension could be overcome, capital would have to be accumulated sufficient to enable the 85 percent of the world that is not presently industrialized to come up to the degree of capital intensiveness of the 15 percent of the world that is industrialized. Within the industrialized countries, capital would have to be accumulated sufficient to enable every factory, farm, mine, and store to increase its degree of capital intensiveness to the point presently enjoyed only by the most capital-intensive establishments, and, at the same time, to enable all establishments to raise the standard of capital intensiveness still further, to the point where no further reduction in costs of production or improvement in the quality of products could be achieved by any greater availability of capital in its vertical dimension.

This would mean the maximum possible use of machinery and automation. It would mean going so far that, for example, canals would frequently be built without locks, because capital would be available simply to remove all the interfering higher elevations. By the same token, every curve and grade would have to be eliminated from railroads and highways, all the whiskey and wines produced would have to be aged to the point where no additional aging could improve them further, and even the enormous growing time of redwoods would cease to be an obstacle to their planting. Capital would also have to be accumulated to the point where no further gain attached to the expansion of the more capital-intensive industries relative to the less capital-intensive industries. This would entail a growth in industries such as housing, the electric utilities, and bridge, tunnel, and canal build-

ing up to their maximum possible limits relative to less capital-intensive industries.

Capital would have to be accumulated to the point where absolutely no project representing an economic improvement was left undone for a lack of capital, however enormous the amount of capital required. This includes projects that today belong in the realm of science fiction because of the vast amounts of capital that would be required for their execution: for example, digging tunnels not only under the English Channel, but under the various seas and even oceans of the world; making inland cities like Phoenix, Arizona, into seaports through the construction of massive canals, and thereby achieving substantial reductions in transportation costs for all time to come; virtually eliminating freight costs between cities, such as New York and Chicago, say, by constructing straight-line tunnels between them that would constitute secants relative to the earth's circumference, with the result that objects would simply be pulled by the force of gravity to the center of the tunnels and, in a frictionless vacuum, hurled to the opposite surface by the force of inertia. Indeed, it may be that some of these projects would even achieve such great cost savings as to yield a substantial rate of return on the capital that would have to be invested, but cannot be undertaken at present because, in the actual state of capital accumulation, they would strip the rest of the economic system of too much of its capital.

The accumulation of capital in its vertical dimension can never remotely begin to exhaust the uses for such capital. Its accumulation always ceases far short of that point. It is always necessary to leave undone an incalculable range of potential improvements whose execution would require a more abundant accumulation of capital in its vertical dimension than exists. Thus, capital in its vertical dimension, as well as in its horizontal dimension, remains permanently scarce.³¹

Such capital accumulation comes to an end because of time preference. Once people succeed in accumulating a certain amount of capital relative to their incomes, they feel that they have done their duty by the future and can now turn more heavily toward enjoying life in the present. Thus, they stop accumulating capital relative to their incomes, even though the accumulation of still more capital relative to their incomes would provide them with still higher incomes in the future.

A Word on Capital Accumulation and the Rate of Return

As stated, later discussion in this book will show that the gains from a lower time preference are both profoundly important and cumulative in their significance, in that they permit the adoption of technological methods

of production that would not otherwise be economically feasible. It will show that the adoption of the more advanced methods of production made possible by a lower degree of time preference is itself a further source of capital accumulation, with the result that capital accumulation does not require steadily repeated reductions in time preference, but is perfectly consistent with an unchanged state of time preference, provided it is sufficiently low. A still lower time preference will be shown to result in an *acceleration* of the rate of capital accumulation.³²

Furthermore, the fact that a lower degree of time preference accelerates the rate of economic progress will be shown to result in a positive addition both to the real and to the nominal (viz., monetary) rate of profit and interest. Thus, the almost universally held opinion among economists that capital accumulation must be associated with a falling rate of return on capital will be challenged. Capital accumulation will be shown not only not to require a falling rate of return, but, as I say, to the extent that it results in a more rapid increase in the supply of goods and money, to result in an addition to the real and nominal rate of return.³³

Time Preference, Rationality, and Freedom

Our previous discussion of the philosophical foundations of capitalism and economic activity implies that time preference is the lower the more rational and the freer a society is.³⁴ The more rational people are, the more are they aware of the future: the more they can mentally project it and the greater is the reality for them of such projections; in addition, the more are they aware of themselves as self-responsible causal agents, capable of affecting the course of future events to their own advantage by means of saving. Similarly, to the degree that people are free and enjoy the security of property, they know that they can benefit from whatever provision for the future they decide to make in the present. Thus, to the degree that a society is dominated by the values of reason and freedom, the more conducive it is psychologically and politically to saving and providing for the future, which is only another way of saying that it is more conducive to a low time preference and to all that that implies about capital accumulation and economic progress.

8. Wealth and Labor

Wealth is the result of human labor. Labor is the means by which man's mind transmits his designs and purposes to matter. It is man's application of his bodily and mental faculties for the purpose of altering matter in form or location and thereby making the matter thus altered serve

a further purpose. Matter thus altered by man's labor is a *product*. Production is the process of thus altering matter. A producer is one who effects such alterations.³⁵

The matter which is altered in production, that is, which is the subject of man's labor, can be nature-given, such as a piece of land or ore in the ground, or itself a previously produced product, such as cotton cloth or steel sheet. Always, the performance of human labor is essential to production.

It is important to realize that in a division-of-labor society, the labor applied in production is not limited to manual labor, that is, to labor applied to materials or otherwise in physical operations. In such a society, it embraces much more, such as the labor entailed in founding, organizing, and directing business firms and in providing them with capital. Such labor achieves its effects by operating through the manual labor of others, which it renders more efficient.³⁶

The concept of wealth embraces not only products but also natural resources, such as land, and mineral deposits in the ground. The physical matter of which natural resources are composed is, of course, not made by man—it is nature-given. Nevertheless, the *wealth-character* of natural resources is man-made: it is the result of human labor. It is the result of the labor that discovers the uses to which the natural resources can be put, and of the labor that enables them to become accessible in ways in which they can be used gainfully. Thus, it is labor that establishes the character of natural resources as goods and thus as wealth. As the leading historical example of this fact, one need only consider that all of the land and mineral deposits of North America were present at the time of the American Indians. Nevertheless, hardly any of that land and mineral deposits then constituted wealth. The land and mineral deposits did not constitute wealth, because the necessary labor—mainly of an intellectual character—had not yet been performed to render them wealth.

The Scarcity of Labor and Its Ineradicability

Wealth not only is the product of human labor, but also could be produced in larger quantity if more labor were devoted to its production. Indeed, the application of more labor is the only fundamental requirement for increasing the supply of wealth. This is because more labor is the source of additional equipment and materials, including additional agricultural commodities and mineral supplies extracted from the ground. Thus, the scarcity of wealth implies a more fundamental *scarcity of labor*.

As has already been shown, and will be fully confirmed in the next chapter, the fact that the wealth-character of natural resources is the result of labor indicates that in a capitalist society, the supply of natural resources

can be indefinitely expanded and therefore does not constitute a long-run limitation on the ability to produce that is independent of the supply of labor. Indeed, as the next chapter will show, even within very short periods of time—weeks or months—the supply of raw materials can almost always be increased through the application of more labor.³⁷

The fundamental scarcity of labor is manifest in the fact that virtually everyone would like to enjoy an income many times greater than the income he is presently capable of earning. For example, today an average worker may earn on the order of \$20,000 per year for working forty hours a week. If such a worker had it in his power to earn \$100,000 per year, he would have no difficulty in finding ways to live up to such an income. Unfortunately, to earn such an income at his present rate of pay, he would have to work more hours than there are in the week. His maximum actual ability to work is obviously vastly less than corresponds to the income he would like to have.

But this is only another way of saying that the utmost goods and services he is capable of *producing* are far less than the goods and services he would like to consume. Taken collectively, our desire to be able to spend five or ten times more than we now can afford to spend is an indication that we would like five or ten times more work performed than is now performed. In the present state of technology and productivity of labor (output per unit of labor), this is how much additional labor would need to be performed to produce the larger volume of output we would like to be able to buy.

Consider. It would be very easy for the government of the United States to arrange things so that the average worker could earn and spend \$100,000 a year instead of \$20,000 a year. Indeed, the governments of many countries have long ago made it possible for all of their citizens to be millionaires! To accomplish such results, all the government would have to do is print enough new and additional paper money. But there is nothing to be gained from such a procedure. It is accompanied by rising prices, which prevent the higher incomes from having any greater buying power than the smaller incomes did before. The only way that earning and spending \$100,000 a year instead of \$20,000 a year can represent the ability to buy five times more goods is if five times more goods are produced. Only then would prices not rise in the face of five times more spending to buy goods. But in a given state of technology and productivity of labor, this would be possible only if five times as much labor could be performed, which, of course, is itself impossible. People can work themselves to the point of utter exhaustion, and still they cannot produce more than a small fraction of all that it would be useful and desirable for them to produce. Thus, the supply of labor that people

can provide falls radically short of the supply whose products they would like to have. Labor is scarce.

(It should be obvious that the scarcity of labor implies there is never any *metaphysical* reason for the existence of unemployment—that is to say, there is never any reason for it by virtue of the necessary, inescapable nature of things. Unemployment belongs strictly in the category of the man-made. Either it is voluntary and chosen by the individuals concerned, because they prefer to wait to find better terms of employment or because they simply prefer leisure; or, where it is involuntary and unchosen by the individuals concerned, it is *forcibly imposed on them*. Unemployment is forcibly imposed through the imposition of too high a level of money wage rates by the government or by coercive labor unions operating with the sanction of the government. These policies, of course, could be done away with. The causes of unemployment will be fully clear once we understand the principles governing money and spending, and the fact that under the freedom of competition, purchasing power sufficient to buy all the goods and services that can be produced in the economic system at the point of full employment is automatically generated by the process of production itself. The discussion of these important matters is reserved for later chapters.³⁸)

The scarcity of labor, of course, is also the result of a scarcity of personal services. Virtually everyone, if he could afford it, would like to be able to be served by maids, cooks, gardeners, personal secretaries, and so on. Each individual could probably find worthwhile uses for the labor of half a dozen or more full-time servants, without even giving the matter more than a moment's thought.

The labor that we implicitly desire to have at our disposal, whether to produce goods for us or to provide us with personal services, is, as I have said, limited only by our imaginations. And yet while nature has provided each of us with an imagination capable of forming desires on a grand scale, it has simultaneously equipped each of us with only two arms to provide for the satisfaction of those desires. Each of us is easily capable of forming desires whose fulfillment requires the labor of multitudes, and yet by the laws of arithmetic, the average member of any society can never obtain more than the labor, or products of the labor, of just *one* person. This is so because for each person who exists to consume, there can be no more than one person present to produce. Indeed, when the very young and the sick and infirm are allowed for, who can only be supported by the labor of others, it turns out that for each person who consumes there is, on average, substantially less than the labor of one person available to produce.

The preceding discussion demonstrates the existence

of a fundamental scarcity of labor. The scarcity of labor is not only fundamental, however. It is also *ineradicable*.

I have already shown earlier in this chapter how increases in the ability to produce are accompanied by new and additional desires for wealth, which grow out of the very same technological advances that make possible the increases in the ability to produce. The effect of this is that the scarcity of labor is not reduced by increases in the productivity of labor. The scarcity of labor is also not reduced by any increase in the size of the population and thus the number of people able and willing to work, because the additional members of that population bring with them their own needs and desires for goods and services that are in excess of their ability to add to the supply of goods and services. Furthermore, as the productivity of labor rises and increases the workers' standard of living, the workers tend to acquire a growing desire for leisure. As a result, not only does the desire for wealth grow as the ability to produce it increases, but also the amount of labor the individual is willing to perform decreases. This represents an additional cause of the continuing scarcity of labor.

Thus, the fundamental and essential nature of economic life is this: the need and desire for additional wealth are there and the nature-given means of producing it are there; all that is lacking is the ability of human labor to transform the nature-given means of production into additional wealth.

On this foundation, the fundamental economic need of rational beings emerges as the overcoming of the limitations on production imposed by the scarcity of labor. Always, what stands between man and his need for greater wealth is his limited ability to produce wealth—his limited ability and also willingness to perform labor. There is only one solution to this problem. And that is *continuously to raise the productivity of labor*—that is, continuously to increase the quantity and quality of the goods that can be produced per unit of labor, including the variety of goods. An ineradicable scarcity of labor resulting from a need and desire for labor that are always vastly greater than the supply of labor requires that the productivity of labor be rendered greater and greater. The rise in the productivity of labor is the only conceivable way in which man can obtain the progressively greater amounts of wealth that his rational and progressive nature requires.

The problem of precisely *how continuously to raise the productivity of labor*, to make possible an ever increasing production and enjoyment of goods per capita, is what I call *the economic problem*.

(Associated with the economic problem is an important but subsidiary problem, which is often mistakenly presented as the central economic problem, namely, how

to allocate an existing limited ability to produce in accordance with the choices of individuals to satisfy their more important wants ahead of their less important wants. The necessity of this choice is implied by the existence of needs and wants that have no limit, in the face of a productivity of labor that at any given time is always strictly limited. Regrettably, it is this subsidiary problem that most economists have in mind when they describe economics as focusing on “the allocation of scarce means among competing ends.” Closely associated with this mistaken view of the economic problem is the formulation of the fundamental problem of economic life in terms of a scarcity of *goods*. The actual fundamental problem, of course, is a scarcity of *labor* and thus how to raise the productivity of labor.)

The next chapter provides a conclusive demonstration of the limitless potential of natural resources and contains a necessary critique of the objections of the ecology movement to economic progress. Following it, Chapter 4 will explain why the focal point of the ongoing solution to the economic problem is *the division of labor*. The division of labor will be shown to constitute the indispensable social-organizational framework for the progressive increase in the productivity of labor required by

man’s nature as a rational being. It will be shown to represent in its inner nature the form of society required for the efficient and progressively improving use of man’s mind, body, and nature-given environment in production.

As previously indicated, subsequent chapters will then show the dependence of the division of labor on the leading institutions of a capitalist society, above all, private ownership of the means of production and the price system. They will also show the reciprocating and thoroughly benevolent influence of the division of labor on private ownership of the means of production and other essential institutions of capitalism, namely, economic inequality and economic competition. Still later chapters will show how, within the framework of the division of labor and capitalism, the productivity of labor is continuously increased on the basis of *capital accumulation*—which entails the employment of ever increasing amounts of wealth as means of further production—and the absolute dependency of this process too on the institutions of capitalism.

In effect, the remainder of this book can be summarized as demonstrating a single proposition: in every possible way, with no valid objection, *the solution for the economic problem is capitalism*.

2. Cf. Ludwig von Mises, *Planning For Freedom*, 4th ed. enl. (South Holland, Ill.: Libertarian Press, 1980), p. 65.
3. For elaboration of these points, see below, pp. 673–674.
4. See below, pp. 378–380.
5. Exactly the same principles apply to the market value of trade secrets. For a discussion of why, unlike government licenses, patents and copyrights do not constitute a case of monopoly, see below, pp. 388–389. For discussion of the status of rights and relationships in general in relation to the concepts of goods and wealth, see Eugen von Böhm-Bawerk, *Whether Legal Rights and Relationships Are Economic Goods in Shorter Classics of Böhm-Bawerk* (South Holland, Ill.: Libertarian Press, 1962).
6. Slavery also undermines the production of wealth by undermining the accumulation of capital. On this point, see below, pp. 455–456.
7. Menger would have disputed the need to include the qualification concerning the expenditure of labor or effort in the definition of economic goods. Nor did he think it necessary to include the qualification “gainfully” in his discussion of “sufficient command” over things. Cf. Carl Menger, *Principles of Economics*, trans. and ed. James Dingwall and Bert F. Hozelitz (Glencoe, Ill.: The Free Press, 1950), pp. 51–54, 100–101.
8. Stocks, bonds, and bank deposits are such claims.
9. Cf. Menger, *Principles of Economics*, pp. 55–58.
10. See below, pp. 141–144.
11. See Israel M. Kirzner, *The Economic Point of View* (New York: D. Van Nostrand, 1960), pp. 22–29, 108–185, for an

exposition of this belief.

12. Regrettably, this criticism applies to the great von Mises and his efforts to portray economics as merely the “hitherto best developed part” of an allegedly wider science of human action known as praxeology. See Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 1–10 passim. I wish to note, indeed to stress, however, that even when I have ultimately come to disagree with some position of von Mises, as in this case, I do not recall ever having read so much as a single paragraph of his writings that did not serve as the most powerful stimulus to my own thinking. Therefore, I urge everyone to give the most serious consideration to every portion of his writings.

13. Adam Smith, *The Wealth of Nations* (London, 1776), bk. 1, chap. 11, pt. 2; reprint of Cannan ed. (Chicago: University of Chicago Press, 2 vols. in 1, 1976), 1:183.

14. For a discussion of the essential elements of a rational philosophy which pertain to economic activity, see above, pp. 19–21.

15. For a presentation of the doctrine of cultural relativism by one of its leading advocates, see Melville J. Herskovits, *Cultural Relativism Perspectives in Cultural Pluralism* (New York: Random House, 1972). For a presentation of the doctrine of conspicuous consumption by one of its leading advocates, see Thorstein Veblen, *The Theory of the Leisure Class* (New York: Modern Library, 1934), chap. 4.

16. I am indebted to Ayn Rand both for the general concept of an objective code of values based on man’s life as the standard and for the special application of that concept in the form of

some goods being classified as being of greater “philosophically objective value” than others. See Ayn Rand, *Atlas Shrugged* (New York: Random House, 1957), pp. 1012–1023; *Capitalism: The Unknown Ideal* (New York: New American Library, 1966), pp. 16–17.

17. See my pamphlet *Education and the Racist Road to Barbarism*, 3d and subsequent printings (Laguna Hills, Calif.: The Jefferson School of Philosophy, Economics, and Psychology, 1992), pp. 4–5. As I wrote in that pamphlet, “Reference to an objective superiority of one civilization or culture over another encounters the opposition of a profound, self-righteous hatred of the very idea. Thus, cultures may practice ritual sacrifice, cannibalism, mass expropriation, slavery, torture, and wholesale slaughter—all of this is accepted as somehow legitimate within the context of the culture concerned. The only alleged sin, the only alleged act of immorality in the world is to display contempt for such cultures, and to uphold as superior the values of Western culture. Then one is denounced as an imperialist, racist, and virtual Nazi. It should be realized that those who take this view do not regard as the essential evil of Nazism its avowed irrationalism, its love of force and violence, and its acts of destruction and slaughter. All this they could accept, and do accept in the case of other cultures, such as that of primitive tribes, ancient Egypt, the civilization of the Aztecs and Incas, the Middle Ages, and Soviet Russia. What they hold to be the evil of Nazism was its assertion that Nazi culture was superior to other cultures. Needless to say, of course, it is only on the basis of the recognition of objective values that one can seriously condemn Nazism—not for its absurd claims of superiority, but as a primitive, barbaric culture of the type one would expect to find among savages.” (Ibid., pp. 7–8.)

18. The flagrant contradiction of upholding individual rights in the midst of Negro slavery has already been noted. See above, p. 28.

19. Cf. Eugen von Böhm-Bawerk, *Capital and Interest*, 3 vols., trans. George D. Huncke and Hans F. Sennholz (South Holland, Ill.: Libertarian Press, 1959), 2:143–145.

20. Cf. John Kenneth Galbraith, *The Affluent Society* (Boston: Houghton Mifflin, 1958), chap. 10. See also, in opposition, George Reisman, “Galbraith’s Modern Brand of Feudalism,” *Human Events* 18, no. 6, sec. 5 (February 3, 1961), pp. 77–80.

21. Again, see below, pp. 414–416.

22. See, for example, Paul Samuelson and William Nordhaus, *Economics*, 13th ed. (New York: McGraw-Hill, 1989), p. 450.

See also above, the Introduction, n. 15, for an explanation of why my references are typically to the 13th edition of Samuelson and Nordhaus rather than to the more recent 14th edition.

23. For a full discussion of Say’s Law, see below, pp. 559–580.

24. See below, pp. 561–569.

25. An illustration of this principle is the devastating storms which occurred in Bangladesh in 1992. Had the same storms occurred in a more prosperous country, in which people could afford concrete houses instead of thatched huts, and in which adequate sea walls could be built, the death toll would have been in the hundreds, rather than over one hundred thousand. See “Even in Bangladesh’s Storms, Poverty Is Underlying Killer,” *New York Times*, May 11, 1991, p. 1, p. 5. Unless otherwise noted, throughout this book all references to this publication are to the national edition.

26. For further discussion of the role of wealth in the lengthening and enrichment of human life, see below, pp. 76–78.

27. Capital is wealth employed in the production of wealth. In the context of a division-of-labor, monetary economy, it is the wealth employed by business enterprises, that is, means of production which have been purchased for the purpose of producing goods or rendering services which are intended to be sold. For further elaboration on the meaning of the concept, see below, pp. 445–456.

28. See Böhm-Bawerk, *Capital and Interest*, 2:268–273.

29. See below, pp. 743–744.

30. See below Chapter 17, in particular pp. 824. See also pp. 629–631.

31. Later discussion will show that the capitalized value of land also contributes to the ineradicable scarcity of capital. See below, pp. 856–857.

32. See below, pp. 813–824.

33. See below, pp. 813–826.

34. See above, pp. 19–21.

35. Depending on the extent of the alteration of the matter, the product may be described either as a new good or merely as the alteration of an existing good. On this point, see below, p. 130.

36. For elaboration of this very important subject, see below, pp. 462–464 and 475–485.

37. See below, pp. 63–71.

38. See below, Chapters 12–19.

CHAPTER 3

NATURAL RESOURCES AND THE ENVIRONMENT

PART A

NATURAL RESOURCES

1. The Limitless Potential of Natural Resources

The potential for economic progress is in no way limited by any fundamental lack of natural resources. Despite the claims so often made that we are in danger of running out of natural resources, the fact is that *the world is made out of natural resources*—out of solidly packed natural resources, extending from the upper limits of its atmosphere to its very center, four thousand miles down. This is so because the entire mass of the earth is made of nothing but chemical elements, all of which are natural resources. For example, the earth's core is composed mainly of iron and nickel—millions of cubic miles of iron and nickel. Its oceans and atmosphere are composed of millions of cubic miles of oxygen, hydrogen, nitrogen, and carbon, and of lesser, but still enormous, quantities of practically every other element. Even the sands of the Sahara desert are composed of nothing but various compounds of silicon, carbon, oxygen, hydrogen, aluminum, iron, and so on, all of them having who knows what potential uses that science may someday unlock. Nor is there a single element that does not exist in the earth in millions of times larger quantities than has ever been mined. Aluminum is found in some quantity practically everywhere. There are immense quantities even of the very rarest elements,

such as gold and platinum, to be found floating in trace amounts throughout the oceans, for example.

What is true of the earth is equally true of every other planetary body in the universe. Insofar as the universe consists of matter, it consists of nothing but chemical elements, and thus of nothing but natural resources.

Nor is there any fundamental scarcity of energy in the world. More energy is discharged in a single hurricane than mankind produces in an entire year. Nor is the supply of energy in the world reduced in any way by virtue of the energy man captures from nature. Heat from the sun provides a constantly renewed supply that is many millions of times greater than the energy consumed by man. The total quantity of energy in the world remains a constant, for all practical purposes incalculably in excess of what mankind consumes, and will remain so until the sun begins to cool.

The problem of natural resources is in no sense one of intrinsic scarcity. From a strictly physical-chemical point of view, *natural resources are one and the same with the supply of matter and energy that exists in the world and, indeed, in the universe*. Technically, this supply may be described as finite, but for all practical purposes it is infinite. It does not constitute the slightest obstacle to economic activity—there is nothing we are prevented from doing because the earth (let alone the universe) is in danger of running out of some chemical element or other, or of energy.

The problem of natural resources is strictly one of *useability, accessibility, and economy*. That is, man needs to know what the different elements and combinations of

elements nature provides are good for, and then to be able actually to get at them and direct them to the satisfaction of his needs without having to expend an inordinate amount of labor to do so. Clearly, the only effective limit on the supply of such *economically useable* natural resources—that is, natural resources in the sense in which they constitute *wealth*—is the state of scientific and technological knowledge and the quantity and quality of capital equipment available.

Because the supply of resources provided by nature is one and the same with the supply of matter and energy, the supply of economically useable natural resources is capable of virtually limitless increase. It increases *as man expands his knowledge of and physical power over the world and universe*.

For example, petroleum, which had been present in the ground for millions of years, did not become an economically useable natural resource until the second half of the nineteenth century, when uses for it were discovered. Aluminum, radium, and uranium also became economically useable natural resources only within the last century or so. The economic useability of coal and, more recently, silicon, has been enormously increased by the discovery of new and additional uses for them.

The supply of economically useable natural resources is increased not only by the discovery of uses for things previously thought to have no uses, or new and additional uses for things already known to have uses, but also by advances that enable man to improve his access to things—for example, to mine at greater depths with less effort, to move greater masses of earth with less effort, to break down compounds previously beyond his power, or to do so with less effort, to gain access to regions of the earth previously inaccessible or to improve his access to regions already accessible. All of these increase the supply of economically useable natural resources. All of them, of course, at the same time bestow the character of goods and wealth on what had before been mere things.¹

Today, as the result of such advances, the supply of economically useable natural resources is enormously greater than it was at the beginning of the Industrial Revolution, or even just one or two generations ago. Today, man can more easily mine at a depth of a thousand feet than he could in the past at a depth of ten feet, thanks to such advances as mechanical-powered drilling equipment, high explosives, steel structural supports for mine shafts, and modern pumps and engines. Today, a single worker operating a bulldozer or steam shovel can move far more earth than hundreds of workers in the past using hand shovels. Advances in reduction methods have made it possible to obtain pure ores from compounds previously either altogether impossible to work with or at

least too costly to work with. Improvements in shipping, railroad building, and highway construction have made possible low-cost access to high-grade mineral deposits in regions previously inaccessible or too costly to exploit.

In the light of such facts, one should consider how foolish it is to complain, for example, that today copper ores are being mined which contain only 1 percent pure copper, whereas at the beginning of the twentieth century the ores mined often contained 10 percent pure copper. With a worker in the cab of a steam shovel able to move hundreds or thousands of times more earth in the same time as a worker with a hand shovel, the volume of pure copper moved in the same time is now enormously greater, even with ores only one-tenth as pure. The resort to such ores is evidence not that we are running out of supplies, but that we have been able to create vastly greater sources of supply than ever before. The very fact that we exploit such deposits is evidence of the advances that have been made. For we would not exploit them in the absence of vast improvements in the productivity of labor.

Similarly, the development of chemical fertilizers and low-cost methods of irrigation have enabled man not only radically to improve the productivity of arable land, but actually to *make more arable land*. Today, land previously desert or semidesert has been made vastly more productive than the very best lands available to previous generations. Israel and California provide leading examples.

There is no limit to the further advances that are possible. Hydrogen, the most abundant element in the universe, may turn out to be an economical source of fuel in the future. Atomic and hydrogen explosives, lasers, satellite detection systems, and, indeed, even space travel itself, open up limitless new possibilities for increasing the supply of economically useable mineral supplies. Advances in mining technology that would make it possible to mine economically at a depth of, say, ten thousand feet, instead of the present much more limited depths, or to mine beneath the oceans, would so increase the portion of the earth's mass accessible to man that all previous supplies of accessible minerals would appear insignificant in comparison. And even at ten thousand feet, man would still, quite literally, just be scratching the surface, because the radius of the earth extends to a depth of four thousand *miles*.

As just indicated, equally dramatic advances are possible in the field of energy. These may occur through the use of atomic energy, hydrogen fusion, solar power, tidal power, or thermal power from the earth's core, or still other processes as yet unknown. Reductions in the cost of extracting petroleum from shale and tar sands have the

potential for expanding the supply of economically useable petroleum by a vast multiple of what it is today. The physical volume of petroleum present in such formations in our own Rocky Mountain states and in Canada far exceeds the liquid petroleum deposits of the Arab countries. All that is required is ways to reduce the costs of extraction.² Similarly, there are also vast known coal fields in the United States containing enough coal to supply present rates of coal consumption for many centuries, and already capable of doing so economically. Since most petroleum products can be made from coal, reductions in the cost of using coal for this purpose would represent the equivalent of a further enormous increase in the supply of economically useable petroleum deposits.

Because the earth is literally nothing but an immense solid ball of chemical elements and because man's intelligence and initiative in the last two centuries were relatively free to operate and had the incentive to operate, it should not be surprising that the supply of useable, accessible minerals today vastly exceeds the supply that man is economically capable of exploiting. In virtually every case, there are vast *known* deposits of minerals which are not worked, because it is not necessary to work them. Indeed, if they were worked, there would be a relative overproduction of minerals and a relative underproduction of other goods—that is, a waste of capital and labor. In virtually every case, it is necessary to choose *which* deposits to exploit—namely, those which, by virtue of their location, the amount of digging required, the degree of concentration and purity of the ore, and so forth, can be exploited at the lowest costs. Today, enormous mineral deposits lie untouched which could be exploited with far less labor per unit of output than was true of the very best deposits exploited as recently as a few decades ago—thanks to advances in the state of mining technology and in the quantity and quality of mining equipment available.

So long as men preserve a division-of-labor, capitalist society and are free and motivated to think and to build for the future, the body of scientific and technological knowledge at the disposal of mankind will grow from generation to generation, as will the supply of capital equipment.³ On this basis, man can steadily expand his physical power over the world and thus enjoy an ever greater supply of economically useable natural resources. There is no reason why, under the continued existence of a free and rational society, the supply of such natural resources should not go on growing as rapidly as in the past or even more rapidly.

The ultimate key to the economic availability of natural resources is *motivated human intelligence*, which means: *a capitalist society*. In such a society, large num-

bers of the most intelligent people devote their lives to science, technology, and business. All are highly motivated to increase the supply of economically useable natural resources by the prospect of earning a personal fortune for every significant success they achieve in this regard. No greater guarantee of mankind's ability to enjoy a growing supply of natural resources could be found.

The essential principles pertaining to natural resources can be summarized as follows. What nature provides is a supply of matter and energy that for all practical purposes is infinite. Yet at the same time, nature does not provide a single particle of natural resources in the form of *wealth*. The bestowal of the character of economic goods and wealth on what nature provides is the work of human intelligence. An essential economic task of man is progressively to apply his intelligence to achieve a growing understanding of nature and to build progressively more powerful forms of capital equipment that give him growing physical mastery over nature.

In this process, advances both in knowledge and in capital equipment themselves set the stage for further advances in knowledge and in capital equipment, thereby operating to give man both ever greater understanding and ever greater physical power over nature—provided, of course, that he continues to be rational, that is, continues to think and to act long range. For example, learning arithmetic sets the stage for learning algebra, which in turn sets the stage for learning calculus, and so on. Being able to build the first primitive railroads and steel mills provides the physical capacity for being able to build more and better railroads and steel mills later on. Developing a metallurgical industry sets the stage for developing an electrical industry and appliance industry, which sets the stage for developing an electronics and computer industry, which in turn sets the stage for developing a capacity to launch spaceships, and so on. The combination of increasing knowledge and increasing physical capacities brings a growing fraction of the physical mass of the earth and, indeed, the universe more and more within man's power to serve his ends and thus continually enlarges the fraction of nature that represents economically useable natural resources and thus wealth.

Thus the portion of nature that represents wealth should be understood as a tiny fraction that began as virtually zero and even though it has since been multiplied by several hundredfold, is still virtually zero when one considers how small is the portion of the mass of the earth, let alone of the universe, that is subject to man's control, and how far man is from understanding all aspects and potential uses of what has become subject to his control. To borrow and expand upon Ayn Rand's statement that the good is an aspect of reality in relation

to man: For all practical purposes, nature in its infinity will forever remain something far more of whose good in relation to man remains to be discovered and achieved than ever has been discovered and achieved, with the essential requirements of the ongoing process being reason and capitalism.⁴ Reason and capitalism achieve a progressive enlargement of the goods- and wealth-character of nature and thus a continually increasing supply of economically useable natural resources. Not only can no greater guarantee of mankind's ability to enjoy a growing supply of natural resources be found, but the underlying metaphysics of a virtually infinite nature that is confronted by motivated human intelligence, which steadily expands both man's knowledge and his physical capacities, ensures that no greater guarantee of mankind's success is necessary.

The growing threat to the supply of natural resources that people are beginning to complain of is not the result of anything physical—no more than it was when these terrible words of despair were written:

You must know that the world has grown old, and does not remain in its former vigour. It bears witness to its own decline. The rainfall and the sun's warmth are both diminishing; the metals are nearly exhausted; the husbandman is failing in the fields, the sailor on the seas, the soldier in the camp, honesty in the market, justice in the courts, concord in friendships, skill in the arts, discipline in morals. This is the sentence passed upon the world, that everything which has a beginning should perish, that things which have reached maturity should grow old, the strong weak, the great small, and that after weakness and shrinkage should come dissolution.⁵

That passage is not a quotation from some contemporary ecologist or conservationist. It was written in the *third century*—long before the first chunk of coal, drop of oil, ounce of aluminum, or any significant quantity of any mineral whatever had been taken from the earth. Then as now, the problem was not physical, but philosophical and political. Then as now, men were turning away from reason and toward mysticism. Then as now, they were growing less free and falling ever more under the rule of physical force. That is why they believed, and that is why people in our culture are beginning to believe, that man is helpless before physical nature. There is no helplessness in fact. To men who use reason and are free to act, nature gives more and more. To those who turn away from reason or are not free, it gives less and less. Nothing else is involved.

The Energy Crisis

There has been much talk about an energy shortage. There is obviously no shortage of energy in nature and no inherent reason why mankind should not be able to

continue the progress of the last two centuries and gain economical access to more and more of nature's virtually infinite supply of energy.

Even if liquid petroleum deposits were to run out in the next fifty years or so, there is no reason why, before they did, men should not be able to produce petroleum products from shale, tar sands, or coal with less labor than they presently produce them from liquid petroleum—just as they presently produce iron and copper from relatively low-grade ores with far less labor than they used to produce them from higher-grade ores. Indeed, petroleum products today can already be produced from these sources with far less labor than they could be produced from liquid petroleum deposits in the past. The power of man's mind, operating in the context of a division-of-labor, capitalist society is clearly such as to leave no doubt that comparable beneficial results could be accomplished with respect to petroleum products in the years ahead.

The energy crisis of the 1970s was purely political. In essence, it was the result of making it largely *illegal* to produce energy. In almost every foreign country, the ownership of oil and natural gas deposits, and thus the production of oil and natural gas, has been made a monopoly of the government. It is simply illegal for private citizens to produce these goods and thus their production has been restricted by all the inefficiencies of government ownership.⁶ In the United States, the federal government claims ownership of the continental shelf and the majority of the land area of the Western states. On the basis of these claims, and under the guise of "concern for the environment," it has closed off many of the most promising areas for oil and gas discoveries. It has set them aside as "wildlife preserves" and "wilderness areas," and thus prohibited their development. In these ways and others, to be explained later in this book, the government made it illegal to produce energy. This is the only reason that there was an energy crisis.⁷ The substantial reduction in government interference that took place in the early 1980s, above all, the repeal of price controls on oil, made the energy crisis disappear. The achievement of a fully free market in energy would ensure a resumption of the growing abundance and declining real cost of energy that characterized the Western world in the two hundred years prior to the 1970s.

Regrettably, however, the government's policy of restricting the supply of energy continues. It continues to withdraw ever more territory from exploration and development: virtually the entire continental shelf of the United States is now closed to new oil drilling and further development of Alaskan fields is in doubt. The government even prohibits the use of already existing facilities for producing energy, the two best-known cases being

the Shoreham atomic power plant on Long Island, in New York State, and the Gaviota Oil and Gas Plant near Santa Barbara, California. The Shoreham plant, completed in 1984 at a cost of \$5.5 billion, had the capacity to supply one-third of the power needs of the 900,000-plus homes on Long Island. Nevertheless, it was never allowed to operate beyond the test level, and as of October 1994, its nuclear reactor was actually dismantled.⁸ The Gaviota plant, completed in 1987 at a cost of \$2.5 billion, has the capacity to refine 100,000 barrels of oil per day. But it too has never been allowed to operate, because of environmentalist policies on the part of the State of California and the County of Santa Barbara.⁹

2. The Law of Diminishing Returns

The production of any product requires the use of at least two factors of production, for example, labor and land, or labor, a land site, a factory building, and machinery and material.¹⁰ The combinations of factors of production, of course, can be far more complex, entailing such things as a variety of machines, materials, means of transportation, and fuels both to power the means of transportation and to provide power and light to the factories involved.

Now if all of the factors necessary to the production of a product are increased in the same proportion, such as all of them being doubled, then it is to be expected that the quantity of product produced will also be increased in that proportion, that is, in the present instance, doubled. Usually, however, it is also possible to increase the production of a product by means of increasing the quantity just of some of the necessary factors of production. For example, the quantity of output produced on a farm might be increased by increasing only the quantity of labor, or labor and equipment together, without increasing the quantity of land employed. In manufacturing, it is almost always possible to increase production within existing factories, simply by increasing the quantity of labor, materials, and fuel employed, and thus without increasing either the number or size of the factory buildings or even the quantity of machinery employed.

All such cases constitute the domain of *the law of diminishing returns*, or, as it sometimes called, the law of nonproportional returns. The law of diminishing returns states that under a given state of technological knowledge, the use of successively larger quantities of any factor of production or combination of factors of production in conjunction with a fixed quantity of any other necessary factor or factors of production eventually results in less than proportionate increases in output. For example, a repeated doubling of the labor and capital

applied to a given piece of land must soon result in less than double the output being obtained from that piece of land.

If such were not the case, then the entire world's supply of food could be grown on this one piece of ground. Similarly, the entire world's supply of any given good could be produced within a single factory building. The fact that sooner or later more land and more factory buildings, more of *all* the necessary factors of production, are required for the production of more of anything, is evidence of the existence of diminishing returns. The point is reached where the application merely of more of the factors of production initially allowed to increase—the so-called variable factors of production—results in an amount of additional output that is less than proportional to the additional quantity of the variable factors of production, and, ultimately, in no additional output whatever. Sooner or later, to increase output in the same proportion as the increase in the variable factors of production, or, indeed, to increase it at all, it becomes necessary to increase the quantity of the factors of production that were initially held fixed (the so-called fixed factors of production).

This necessity results from the existence of what von Mises has called "quantitative definiteness." Everything physical has only a definite, delimited capacity to produce effects. That capacity may be exhausted at one fell swoop, or it may be approached more or less gradually. For example, the capacity of a given quantity of flour of a definite quality to produce bread is thoroughly exhausted in the production of a definite quantity of bread of a definite type. It is not possible to produce more such bread without the availability of more such flour. The application of additional labor alone in this case would not result in any additional product.

In other cases, such as loading a flatbed truck higher and higher, it is possible to increase the quantity of labor expended disproportionately and succeed in producing more of the product, in this case more cargo loaded onto a given truck. But again, sooner or later, the carrying of more cargo requires another truck, and before another truck becomes absolutely essential, the carrying of more cargo *relative to the employment of a given amount of labor* requires another truck. This last reflects the fact that disproportionate increases in the quantity of labor are required to accomplish additional increases in the amount of cargo loaded onto a given truck. In both cases, that of the flour and that of the truck, the capacity of the fixed factor of production to render service is limited and sooner or later more of the fixed factor is required for the production of more of the product and/or to maintain the productivity of the variable factor(s) of production.¹¹

Table 3-1 provides a quantitative illustration of the

Table 3-1
Diminishing Returns

Quantity of Labor Employed on a Farm of 100 Acres (in man-years)	Output (in bushels)	Increase in Output	Average Output per Worker
1	100	100	100
2	190	90	95
3	270	80	90
4	340	70	85

operation of diminishing returns in the context of the application of varying amounts of labor to a farm of a given number of acres. It makes clear how more of the fixed factor of production is required to maintain the *productivity* of the variable factor(s) of production long before it is absolutely required for the production of any more of the product whatever. Thus, in Table 3-1, while more output can be produced simply by employing more labor, the use of more land is necessary to stop the productivity of labor from falling. For example, the table shows 85 units as the average output per worker resulting from the employment of 4 man-years of labor on a farm of 100 acres. At the same time, the table implies that with four such 100-acre farms, the average output per worker would be 100 units rather than only 85 units.

The only context in which the law of diminishing returns does not apply is that of technological formulas or recipes, that is, ideas. The same identical idea can be applied over and over, ad infinitum, with absolutely no loss in its ability to render service and thus no decline in the productivity of the other factors of production.¹²

Closely related to the law of diminishing returns is a parallel phenomenon which was identified by the great classical economist David Ricardo, and which operates on the basis of the pursuit of rational self-interest. This is the fact that as far as people have knowledge and the power of choice, they will choose to exploit land and mineral deposits where the productivity of their labor is greatest. As Ricardo put it, they will begin by cultivating land of the first quality and by exploiting mineral deposits of the first quality. Only when population reaches the point where all the land and mineral deposits of the first quality have been brought into production, will they resort to land and mineral deposits of the second quality, which now represents the most productive land and

mineral deposits available to them. In comparison with land of the first quality, land of the second quality will tend to be farther away from the market it serves, to be higher up on the hillsides, and to have rockier soil; mines of the second quality will also tend to lie farther away from the market they serve, and to have less pure ores and require deeper digging.

Further increases in population and the bringing into production of more and more of the land and mineral deposits of the second quality ultimately results in the need to exploit land and mineral deposits of the third quality, which at that point are rendered the most productive still available, and, after that, land and mineral deposits of the fourth, and still lower qualities. Thus, a man-year of labor performed on land of the first quality may result in an output of 100 units, while an identical man-year of labor performed on land of the second quality results in an output of 90 units, and on land of the third quality, 80 units, and, finally, on land of the fourth quality, only 70 units.¹³

The necessity of progressively resorting to land of inferior degrees of productivity operates in just the same way as the diminution of returns accompanying the employment of more and more labor on any given piece of land. Indeed, the two processes go on side by side. In the examples presented here, when it became necessary to cultivate land of the second quality, land of the first quality would be cultivated more intensively, and the additional output gained by the employment of the second man-year on land of the first quality would equal the output produced by the first man-year on land of the second quality, namely, 90. Similarly, when it became necessary to cultivate land of the third quality, land of the second quality would be cultivated more intensively, and the cultivation of land of the first quality would be further intensified. In our examples, the output of the first man-year

on land of the third quality is equal to that of the second man-year on land of the second quality and to that of the third man-year on land of the first quality, that is, 80.

The Law of Diminishing Returns and the Limitless Potential of Natural Resources

The law of diminishing returns in no way contradicts the previously established proposition that there is no practical limit to the potential supply of economically useable natural resources. This is because the law of diminishing returns in application to agriculture and mining applies only *at any given time*, in the context of *a given state of technology and capital equipment*. Over time, economic progress can occur. Indeed, in a division-of-labor, capitalist society, with its rationality and its incentives both monetary and cultural for the continuous application of reason to the problems of human life, economic progress is the norm.¹⁴

The advancing technology and improving capital equipment which such a society makes possible can easily offset the effects of the law of diminishing returns, and by a wide margin. Quantitative definiteness continues to exist and it continues to be true that, for example, one can bake just so much bread of a given quality from a given quantity of flour, or generate just so much heat from a pound of coal. However, ways are found for the same quantity of human labor, using improved machinery and equipment, to produce and process larger quantities of flour, coal, and all other goods. Similarly, ways are found for the same quantity of human labor to farm or mine larger quantities of land, and to render larger quantities of land suitable for farming or mining. In farming, this occurs through such means as the use of tractors and harvesters and the development of improved methods of irrigation. In mining, it occurs through such means as the use of steam shovels, bulldozers, improved drills, and high explosives. In addition, as scientific and technological knowledge increases, ways are found radically to increase the productive power of each acre of farmland or mineral deposit. In farming, this occurs by such means as improving the chemical composition of the soil, the use of insecticides and herbicides, developing improved strains of seed, and, of course, once again, irrigation. In mining, it occurs by such means as finding ways to process ores previously impossible to process or too costly to process—for example, acquiring the ability to move multiton loads of ore with less effort than was previously required to move a single shovelful of ore, and learning to break elements out of different compounds or to do so at a lower cost, such as learning to break iron out of sulfide compounds as well as oxide compounds and to do so at a lower cost.

Thus, in a division-of-labor, capitalist society, a more

intensive or more extensive use of land encounters diminishing returns whether in 1894 or in 1994. But in such a society, by 1994 economic progress has so improved the powers of human labor that the very poorest lands and mines currently in use are a hundred times more productive than the very best lands and mines in use in 1894, and the point to which the productivity of labor diminishes in agriculture and mining in 1994 is more than a hundred times higher than the point to which it diminished in 1894. Indeed, thanks to economic progress, it is possible today to take even extremely submarginal land—actual desert—and by piping in water and adding various chemicals to the soil, make such land vastly more productive than were the very best lands of a few generations ago, as has been accomplished in Israel and in the Imperial Valley in California. Similar examples can be found in the case of mining. Indeed, so great has been the access to better lands and the increase in yields per acre on all grades of land, that extensive acreages farmed in the past have been thrown out of cultivation and returned to forest or pasture. This was the case in large portions of the eastern United States as better lands opened up in the Midwest, and in Great Britain, as American lands became a source of supply.

With still further economic progress, such results will continue to be achieved in the future. For example, in recent years, it has been demonstrated that it is even possible to grow many crops in scientifically controlled soils and solutions in multistory buildings, in virtual factory conditions. This, of course, is a development potentially equivalent to a practically limitless increase in the supply of agricultural land. The art of genetic engineering, presently in its infancy, also holds out enormous potential. In the case of mining, it will probably one day be possible with the aid of controlled atomic and hydrogen explosions to move the most enormous masses of earth at a minimum of cost. And it will probably come within man's power someday to conduct mining and even farming operations not only under the sea, but elsewhere in the solar system, and beyond.

Thus, the leading principle continues to be that as man increases his knowledge of and physical power over the world—indeed, the universe—the supply of accessible and economically useable natural resources continues to increase, and to increase per unit of labor expended.

The discussion of the law of diminishing returns confirms the fact that the only limiting factor in production—the only fundamentally scarce agent of production—is human labor, never land or natural resources. There is always uncultivated land that could be cultivated, or already cultivated land that could be cultivated more intensively, and mineral deposits that are known but

presently unexploited, or that are exploited, but which could be exploited more intensively. For example, there is all the land left as natural forest or pasture, which could easily be used to grow crops, and the enormous quantities of desert-type land which potentially could also be used for crops. As an example from the case of minerals, there are, as previously mentioned, enormous deposits of oil in the form of shale and tar sands that have never been touched. And roughly two-thirds of the oil in conventional oil fields has typically been left in the ground.

The reason for leaving such useable land and mineral deposits alone is that the labor that would be required to work them would have to be withdrawn either from better land and mineral deposits, where its productivity is higher, or from the production of other goods that are more important than the production of additional agricultural commodities or minerals. For example, to farm land that we now leave alone, we would have to withdraw labor either from better farmland, where its productivity is higher, or from the production of other goods having greater importance to buyers than the additional agricultural commodities.

For exactly the same reasons, we do not exploit each piece of land or mine to the maximum possible extent. The additional labor that would be required would have to come either from other land or mines where the operation of diminishing returns had not been carried as far, and thus where the productivity of labor is greater, or from the production of other goods having a greater importance to buyers than additional agricultural commodities or minerals. For example, to get all the remaining two-thirds of the oil out of a conventional oil field, we might have to give up the one-third normally extracted from a dozen other oil fields, because we would need so much additional labor. Or we would have to give up other goods in quantities that we judged to be more important than the additional oil.

Nevertheless, it should be clear that if we do need more agricultural commodities or minerals, we can obtain them by withdrawing labor from other lines and applying it to existing farms or mines, or to land or mineral deposits which we know to be capable of production but which we have up to now left idle because their exploitation did not pay. Thus, even in the short run, that is, without waiting for any new technological advances or discoveries, production need never be restricted by a lack of raw materials.

Of course, with economic progress, which is to be expected under capitalism, we can have more and more raw materials, not only without withdrawing labor from other lines, but along with actually making labor available for other lines. The economic history of the last two centuries, for example, shows not only a radical increase

in the supply of raw materials of all types, but also a radical decrease in the proportion of labor devoted to agriculture and mining, and a corresponding increase in the proportion of labor devoted to manufacturing and the various service industries. These results can be understood simply by imagining a hundredfold increase in the productivity of labor in the production of raw materials, accompanied by a willingness to consume only a ten-times greater quantity of raw materials before giving preference to larger quantities of more highly processed goods and to larger quantities of services. In such circumstances, instead of using 100 workers in agriculture and mining to produce 100 times the output of raw materials, 10 such workers will now be used to produce 10 times the output of such goods, and 90 workers previously used to produce such goods will be released to produce more of other things.

Diminishing Returns and the Need for Economic Progress

The existence of the law of diminishing returns implies that economic progress is necessary not only for improvement in the standard of living, but also to maintain the standard of living at any given level. In the absence of economic progress, a rising population would result in diminishing returns in both agriculture and mining, because the larger supply of foodstuffs and minerals that would be required for the larger population would necessitate resorting to land and mines too poor to have been exploited before, and to the more intensive exploitation of the land and mines already in use. Even if the population did not grow, diminishing returns would still be encountered in mining, as the ores closest to the surface and otherwise easiest to work gave out. (In the case of mining, diminishing returns actually accompany the repetition of the same amount of labor over time, not just the application of additional labor at the same time.)

Thus, even with a constant population, *in the absence of economic progress, the standard of living falls rather than remains stationary*. When it does remain stationary, it does so as the result of at least enough economic progress taking place to offset the operation of the law of diminishing returns in mining.

These facts should be of significance in judging the proposals of those who desire an end to economic progress, notably the ever increasing numbers within the environmental or ecology movement who subscribe to the goal of zero economic growth. What they are asking for is not the maintenance of our present level of well-being, but growing impoverishment.¹⁵ Furthermore, it should be realized that such impoverishment cannot be made gradual and gentle, as year-to-year diminishing returns in mining might suggest. Nor is it possible some-

how to arrange for just enough economic progress to offset diminishing returns in mining.

Economic progress is not something that can be controlled or regulated in amount. If the conditions are right for it, there is no fixed limit to how much of it there can be at any time. If the conditions are wrong for it, there will be not only no economic progress, but radical economic decline.

The essential precondition of economic progress is the existence of individuals who are motivated to think and to apply the results of their thinking to the economic world. But this is also an essential precondition of the *maintenance* of any modern economic system as well. To maintain such a system, new problems must constantly be solved. Even if essentially the same problems have been solved before, in previous generations, they are new to those who must solve them in the present generation. And almost always, they will differ in at least some important respects from the problems solved in the past. All machinery and equipment eventually wear out and must be replaced. All buildings, roads, bridges, and tunnels sooner or later need total replacement or such extensive maintenance and repair as to be tantamount to total replacement. All of this requires a fresh process of thought. And this requires the existence of a large body of individuals willing and able to think.

The attempt to stifle the fresh thinking that results in economic progress must, if successful, also stop the fresh thinking that is necessary to maintain the economic system at its present level. This is because it must operate against fresh thinking as such. One cannot tell a self-activating intelligence that it can be driven by its curiosity up to the point of repeating what happens to be the old, but must not undertake the new. If the attempt is made to stifle the curiosity and discovery associated with the new, it must serve to stifle the curiosity and discovery required to replicate the old. The effect of prohibiting economic progress must be to make eager intelligence give way to passive stupidity throughout the economic system, and thus radically to undermine the economic system, not merely prevent its improvement.

3. Conservationism: A Critique

The preceding discussions imply that the doctrine of conservationism is incorrect. Conservationism regards the existing supply of economically useable natural resources as nature-given, rather than as the product of human intelligence and its corollary, capital accumulation. It does not see that what nature provides is, for all practical purposes, an infinite supply of matter and energy, which human intelligence can progressively master, in the process creating a steadily increasing supply

of economically useable natural resources. It does not see that the supply of economically useable natural resources increases as man gains understanding of the world and the universe and correspondingly improves his means of production, thereby progressively enlarging the fraction of nature over which he holds physical power. It does not see that as the fraction of nature within man's knowledge and control grows, so too does his supply of economically useable natural resources. In a word, conservationism does not see that the increase in the supply of economically useable natural resources is part of the very same process by which the ability to produce as such and in general is increased.

Having no conception of the role of human intelligence in the creation of economically useable natural resources, and confusing the present supply with all the natural resources present in nature, the conservationists naïvely believe that every act of production that consumes natural resources is an act of impoverishment, using up an allegedly priceless, irreplaceable treasure of nature. On this basis, they conclude that the pursuit of self-interest by individuals under economic freedom leads to the wanton consumption of mankind's irreplaceable natural heritage, with no regard for the needs of future generations.

Once having arrived at the existence of this altogether illusory problem, the product of nothing more than their own ignorance of the productive process, the conservationists further conclude that what is necessary to solve this alleged problem is government intervention designed to "conserve" natural resources by restricting or prohibiting in various ways mankind's use of them.

Ironically, the consequence of all such restrictions and prohibitions is *waste*—the waste of the one truly scarce factor of production, namely, human labor. It is our labor and our time that are fundamentally scarce, not land or natural resources. It is our labor and our time that we fundamentally need to save, not land or natural resources. For the most part, we need to economize on land and natural resources only insofar as doing so represents a saving of our labor or time. We need to be concerned with those land sites and mineral deposits whose existence saves us labor as compared with having to produce by using inferior land or mineral deposits. For example, we value farmland in the Midwest and an oil field because their existence saves us labor in producing food and oil. Without that midwestern farmland, we would have to produce to a greater extent on less productive East Coast farmland, or cultivate other midwestern land more intensively and thus produce with a lower productivity of labor. Similarly, without that oil field, we would have to resort to more intensive, less efficient methods of extracting oil from other such fields or perhaps bring into

production a less productive source of oil, such as tar sands, or even shale deposits. In both cases, the effect would be that it would take more labor to produce the same amount of goods. The existence of the midwestern land and of the oil field saves us that labor, and that is why we value both.

Sometimes, it is true, particular land sites are unique in *what* they enable us to produce. Their product cannot be perfectly duplicated by using a larger quantity of labor elsewhere. For example, real estate in downtown Manhattan, sturgeon beds providing fine caviar, vineyards serving in the production of grapes, and thus wines, of a unique flavor. At other times, no amount of labor can provide more of a good—for example, agricultural commodities between harvests. In these categories of cases, we may speak of a problem of conservation apart from the saving of labor.

But even in these cases, conservationism is thoroughly mistaken in thinking that some kind of political action is required to avoid misuse of the goods in question. This is because the market price of such goods reserves them to their most important uses and limits the rate of their consumption in conformity with the limited supply of them available. The free-market price of real estate regularly ensures that it is devoted to its most important uses. The free-market price of every agricultural commodity acts to conserve an adequate supply of it until the next harvest comes in. In exactly the same way, the free-market price of minerals operates to limit their rate of consumption between the discovery of new deposits or improved methods of extraction, to whatever extent that may be necessary. In such cases, the prospect of higher prices in the future operates to bring about higher prices immediately, which higher prices automatically limit the rate of consumption.¹⁶ No limitation of the rate of consumption by the government is required. All the necessary limitation is effected by the free-market price, which makes all due allowance for the needs of the future. Any limitation of the rate of consumption over and above that accomplished by the free-market price merely serves needlessly to sacrifice the present to the future, which does not require such sacrifice, and thus simply to render human labor less productive.

The mistaken philosophy of conservationism currently plays a major role in the opposition to atomic power, the strip mining of coal, and the opening of new landfill areas for garbage disposal. It also underlies the many proposals for “recycling” and even the fifty-five mile an hour speed limit.

It is argued, for example, that the disposal of radioactive material from atomic power plants constitutes a major problem because the dump sites in which the material is placed will remain radioactive and therefore

unuseable for other purposes for tens of thousands of years. Similarly, it is argued that the strip mining of coal should not be undertaken because once the coal is removed, the land will no longer be useable for farming or ranching, unless, at great expense, the soil layer is restored.

The supporters of these arguments simply do not realize that we do not need every last piece of land that we possess. In the United States, we have hundreds of thousands of square miles of land—deserts and mountains, for example—that as far as their contribution to human life and well-being is concerned might as well be covered with sea water. The marginal utility or importance of such land is simply zero. Even if some of it were totally lost to use forever, it would make absolutely no difference to human life and well-being. In insisting on the sacredness of every square mile of land, we place ourselves in the position of a kind of irrational miser—not a miser of money, but, if it is possible to imagine it, a miser of water in a country that is filled with lakes, rivers, and streams. It is as though we were a farmer needing, say, a thousand gallons of water a day for every purpose that water can serve, and having ten thousand gallons a day available, and yet losing sleep at night over the loss of a cupful somewhere.

Even if, out of the 3.5 million square miles of territory of the United States, atomic dump sites and surface coal mines totally and forever destroyed the usefulness of a few hundred or even a few thousand square miles for other purposes, there would be no loss to us. Even if some of the land to be used for these purposes presently has other uses, like serving as farmland or ranch land, these uses would be given up only because of the land’s greater value as a dump site or mine. And its loss as farm or ranch land would be made good either by bringing other, presently unused land into production or by producing more intensively on other land. The net effect would simply be that we could have some of the additional energy that we so urgently need.

To make all this concrete and as clear as possible, let us assume that a coal-mining company wants to buy land in Wyoming that is presently a cattle ranch. It is willing to pay a price that is far higher than corresponds to the income its present owner can make from ranching. Neither the coal-mining company nor the rancher nor the great majority of other people may realize it, but this higher offer reflects the fact that this piece of land is more urgently needed for coal mining than for cattle ranching. The buyers of coal are willing to allow more in the price of coal for the use of this piece of land than the buyers of cattle products are willing to allow for it in the price of cattle products. That is why it is worth more to the coal mining company than it is to the cattle rancher. Even if

the piece of land is lost forever to cattle ranching or any other use thereafter, the effect is that we can obtain urgently needed coal and energy, while the cattle the land previously supported can be fed on other land. Furthermore, because of the greater availability and therefore lower price of energy that would result from allowing the all-out development of energy sources, it is almost certain that the cattle would soon be able to be raised at a lower cost on other land than they could be if they continued to remain on the coal-bearing land.

The same principles, of course, apply to atomic dump sites. It should go without saying that, in a capitalist society, the owner of such a dump site would not be able to expose the property of his neighbors to harmful doses of radiation. He would have to own a large enough site to ensure that radiation levels at its perimeter were well within the zone of safety. (It should also go without saying that a landowner's neighbors, let alone people living at the opposite end of the country, have no right to the preservation of any special aesthetic qualities of a piece of land. Even if it were true, for example, that strip mining left the land horrendously ugly, rather than bestowing its own kind of grandeur, no one could legitimately claim that he is thereby denied the use and enjoyment of his own property, or, therefore, that he has a right to interfere.¹⁷)

Of course, it is probably the case that in the future technology will find ways of eliminating radioactivity and restoring land at far less cost than is presently possible. Whether it does or not, however, is irrelevant. For nothing of significance depends on our having the land in question.

As matters now stand, the kind of mistaken ideas about the waste of land that have been discussed are threatening us with an enormous waste of our labor. This is because the only alternative to the energy that man-made fuels such as atomic power and strip-mined coal can provide is the minuscule amounts that human muscles can provide. Thus if we prevent the development of such man-made fuels, our ability to produce is correspondingly impaired.

As indicated, a further consequence of the conservation mentality has been a sharp reduction in the number of government permits issued for the opening of landfill areas for garbage disposal.¹⁸ The conservationists' rationale is that the use of land for this purpose represents a "waste" of the land. The effect has been that as the existing landfill areas approach their planned capacity, a shortage of space for garbage disposal has begun to develop. In response to this shortage, citizens are denounced for a profligate lifestyle, which allegedly generates an excessive amount of garbage, and as part of the solution, parents are urged to sacrifice both their own

convenience and even the comfort and health of their infants by giving up the use of disposable diapers and going back to the use of diaper services. In addition, homeowners and apartment dwellers are urged to turn a portion of their dwelling space into minirecycling centers, carefully separating newspapers, metal cans, and glass containers from ordinary refuse, to make possible the convenient collection and recycling of these items.

As the shortage of landfill space has developed, such facts as the government's restrictions on the opening of new landfill areas have been conveniently ignored in the press, which has led the public to believe that the problem is one of an actual lack of space for garbage disposal. Also ignored is the fact that the average American, with his modern, prosperous lifestyle actually generates substantially *less* garbage today than in the past, and less than the average contemporary Mexican with his much less advanced and highly impoverished lifestyle.¹⁹ This is the result of such facts as that in modern society the twelve hundred pounds or more of coal ash that the average American family used to generate is no longer generated, thanks to the use of electricity, natural gas, and heating oil to heat homes; nor, thanks to such things as canning and freezing and modern meat packing, is there nearly as much garbage for the average family to dispose of in the form of animal and vegetable matter, such as chicken feathers, fish scales, and potato peels. And of the garbage that is generated, it turns out that the contribution made by disposable diapers is on the order of a mere 1 percent, while that of fast-food containers (another leading target of today's conservationists and "environmentalists") is closer to a tenth of 1 percent and that of all plastics combined (yet another leading target) is less than 5 percent.²⁰

Confusions about waste are present in much of the concern expressed about the need for "recycling." When it is possible for a comparative handful of workers using giant steam shovels and other such machinery to move and process ores in multiton loads and thus to produce things like new tin cans and glass jars easily and cheaply, it makes little sense for the average person to spend his time ferreting through his garbage to find a few cans or jars to bring to his neighborhood "recycling center" or to set aside for pickup by a special garbage truck. It is not his throwing away the cans or jars that is wasteful, but his spending time to retrieve and deliver them, or the garbage disposal company's having to make a separate collection of them. For he certainly has better things to do with that time, and the garbage company should not be put to the needless expense of having a second truck and crew to collect items of insignificant value.

Of course, not all recycling is wasteful. Whether it is or not is indicated by the relationship between the market

price of the recycled material and the cost of recycling it. If the market price of the recycled material is high enough to allow compensation for the labor involved and for a competitive rate of profit on the capital that must be invested, then the recycled material is important enough to justify the recycling. For example, the price of gold and silver is high enough to make it pay dentists to retrieve the shavings drilled from fillings, which would otherwise simply be washed down the drain. On the other hand, it normally would not pay people to save their steel or aluminum cans, because the productivity of labor in mining and processing fresh iron and aluminum ore is so high, and the price of steel and aluminum cans accordingly so low, as to make their efforts in this regard highly inefficient and unnecessary.

In this connection, it should be realized that there is nothing “wasteful” or uneconomic in the fact that we use so many cans or so many paper wrappings. As pointed out a few paragraphs back, they actually serve considerably to reduce the volume of the more unpleasant forms of garbage.²¹ Furthermore, as I wrote elsewhere, if we consider how little labor it costs us—in terms of the time it takes us to earn the money we spend for it—to have things brought to us clean and fresh and new, in new containers and new packaging, and what the alternatives are for the spending of that money or the use of that time, it becomes clear that the expenditure is well made.²²

For consider the alternatives. We could have our food and other goods wrapped in old newspapers and put in jars, bags, or boxes that we would have to carry along with us whenever we went shopping, or which we would have to make a special trip to go and fetch whenever we came on something unexpectedly that we wanted to buy. We could then use the money we saved in that way to buy a handful of other goods. Conceivably, we could use the money we saved to work a few minutes less at our jobs each day, and earn correspondingly less. But these alternatives would simply be bizarre, because neither a handful of extra goods nor working a few minutes less at our jobs each day would compensate us for the loss of cleanliness, convenience, aesthetic satisfaction, and also time saved in shopping that is provided by modern packaging.

Of course, people are free to adopt a poverty-stricken personal lifestyle if they choose. They may go about like old Russian grandmothers in Moscow, with an ever present shopping bag and herring jar, if that is what they like. They may pick through garbage pails while pretending that they live in a spaceship—“spaceship Earth,” they call it—rather than in the richest country of the planet Earth. But there is absolutely no sane reason why anyone should, or needs to, live this way, and certainly not in modern America. Above all, no one should be forced by

law to comply with such peculiar values.

Not surprisingly, the attempt to force people to accept such irrational values has begun to introduce what must be described as a measure of totalitarian interference into their lives. Where recycling has become mandatory, as in New York City, there are now garbage police, whose job is to snoop into people’s garbage to make sure that they are complying with the recycling requirements. Such coercion and spying are unavoidable when people are required to do something nonsensical and which they would thus not do voluntarily. It can be expected that school children indoctrinated with environmentalism will be encouraged to report neighbors and even their own parents to the garbage police.

The fifty-five mile-an-hour speed limit is also inspired by conservationism. It is supposed to avoid the waste of oil. As a conservation measure, the fifty-five mile an hour speed limit turns out to be wasteful in the same way that the compulsory recycling measures are wasteful. Namely, in a misguided effort to save oil, it wastes labor, equipment, and people’s time, the loss of which is more important than the oil it saves.

The proof of this wastefulness is that all the trucking companies and most automobile owners know that by driving at fifty-five miles an hour, rather than at seventy miles an hour, say, they can reduce the amount of fuel consumed per mile and thus reduce their fuel costs. Nevertheless, despite this cost saving, they do not voluntarily choose to drive at the lower speed. The reason the trucking companies do not is that the value of the fuel saved is less than the additional wages that must be paid to truck drivers, who must spend more hours driving at the lower speed to haul the same amount of freight the same distance; in addition, a larger number of trucks may be required to haul the same amount of freight within the same period of time. The owners of automobiles do not voluntarily drive at the lower speed, because the importance they attach to the money they would save by doing so is less than the importance they attach to the time they save by driving faster.

The comparison of the money saved with the money lost, or of the importance of the money saved with the importance of the personal time lost, is the only rational criterion of waste, because it weighs *all* the relevant factors involved (such as the truckers’ labor as well as the fuel), not just one factor in isolation. Furthermore, if it is kept in mind that additional oil can always be produced if necessary, by withdrawing labor from the production of other things, then it should come as no surprise that the use of this criterion leads to goods being produced with the lowest overall amount of labor, or with labor of the least value.

The fact, for example, that the fuel trucking compa-

nies can save by driving more slowly is less valuable than the extra truck drivers' labor they need at the lower speeds is an indication that the labor needed to *produce* the additional fuel is less than the labor needed to save fuel by driving more slowly. For example, saving five dollars' worth of fuel by virtue of having to pay ten dollars more in wages to truck drivers is an indication that at least twice as much labor is required to make possible the saving of the fuel than is required to produce an equivalent amount of the fuel. Indeed, since the wages paid in the production of fuel worth five dollars are *less* than five dollars, the saving of labor through the use of the fuel in question turns out to be even greater. The fact that a given amount of fuel can be made available by less labor if we produce more fuel than if we consume less fuel means that conservationism's forcing us to consume less fuel simply makes us waste our labor.²³

Ironically, in previous decades, mistaken ideas about waste led to demands for government-sponsored development of natural resources, above all, irrigation and flood control projects. At that time, it was naïvely assumed that the mere fact that a piece of land was capable of being used productively meant that it should be used productively; otherwise, it was held, the land was "wasted." It was not realized that in view of the fundamental scarcity of labor, it is simply not possible to use all the land that is potentially useable. It was not seen that the effect of compelling the development of land that the market judges to be submarginal is to cause the waste of labor and capital—that is, the withdrawal of labor and capital from better, more productive land or from the production of other goods more urgently desired. On the basis of such ignorance, the U.S. government, under the New Deal, squandered billions of dollars on such projects as the Tennessee Valley Authority.

Conservationism has spawned the popular misconception, now taken up by the ecology movement, that the individual's freedom to pursue his self-interest is responsible for such phenomena as senseless deforestation and the wanton destruction of species. The improper, uneconomic deforestation practiced in various portions of the United States in the late nineteenth and early twentieth centuries, and the near disappearance of the buffalo, which once roamed the Great Plains of the United States in large numbers, are presented as leading examples.

These examples do not prove what the conservationists believe they prove. It was not the pursuit of self-interest under freedom that was responsible for such deforestation, but the government's *violation of the individual's freedom to establish private property*. Since the second half of the nineteenth century, the U.S. government has

claimed ownership of most of the territory of the Western states, including, of course, forests and mineral deposits, and refused to allow this territory to become private property.

When, in contrast, forests are privately owned, self-interest does not normally lead their owners to cut them down without bothering to replant, which is what the logging companies were denounced for in the late nineteenth and early twentieth centuries. Indeed, a self-interested owner does not normally cut trees down without bothering to replant, any more than he cuts down wheat or corn without bothering to replant. Trees are simply a longer-term crop than wheat or corn. They are commercially grown wherever land is private property and the prospective price of trees covers the costs of planting and an allowance for a compound competitive rate of return over their growing life.

However, the fact that the western forests of the United States were owned by the government meant that the logging companies which worked them could not expect to receive the benefits of replanting. As a result, they had no incentive to go to the trouble and expense of replanting. Had the government owned the farmland, and deprived farmers of the prospect of owning the next crop of wheat or corn, no incentive would have existed for replanting those crops either. The obvious solution was to make forest lands private property. Private owners, whether logging companies or others, would have had the incentive to replant.

The near extermination of the buffalo resulted from the fact that their value to man was simply not great enough to justify the expense of the labor of preserving them. The buffalo certainly could have been raised commercially, on ranches, just as cattle are raised. But no one found it profitable to do so, because the consumers were simply unwilling to allow prices for buffalo meat and buffalo hides high enough to cover the costs of such operations. They much preferred beef and cowhides instead. Buffalo were valuable to man only so long as they were free for the taking on the open range.

In the light of such facts, their near extermination was not an act of wanton destruction, but perfectly reasonable. The only alternative would have been to compel the domestication of the buffalo and, to that extent, to force the consuming public to accept buffalo meat and buffalo hides in preference to beef and cowhides. Or else the alternative would have been to close the Great Plains, or some large part of them, to settlement, in order to maintain the open range for the sake of the buffalo. Either way, the preservation of the buffalo as a significant species would have entailed enormous waste: the waste of ranch land, labor, and capital in supporting buffalo herds instead of cattle herds, or the waste of the whole Great

Plains or some huge portion of them in being closed to development altogether. Either way, there would have been an enormous loss in terms of the ability of the Great Plains to contribute to human life and well-being.

PART B

THE ECOLOGICAL ASSAULT ON ECONOMIC PROGRESS

1. The Hostility to Economic Progress

A long-standing hostility has existed to economic progress. Prior to the 1960s, this hostility was based on the doctrines of asceticism, conspicuous consumption, cultural relativism, and on a cluster of economic fallacies to which I have given the name consumptionism. (This last is represented by such beliefs as that machinery causes unemployment and that war and destruction cause prosperity. According to consumptionism, the fundamental problem of economic life is not the creation of wealth but of the need or desire for wealth, which is thought to be naturally limited, and which allegedly has been or is about to be surpassed by the production of wealth, thereby resulting in a problem of “overproduction,” depression, and unemployment.)

The doctrines of conspicuous consumption and cultural relativism have already been dealt with in Chapter 2. Consumptionism is dealt with below, in Part A of Chapter 13. As for asceticism, which claims to find value in self-denial for its own sake, there is nothing to say except that wealth is the means to better health and longer life, as well as to greater enjoyment of life. Thus, its value is logically implied in the very concept of human values, which presupposes the existence of living human beings who value their lives.²⁴ Moreover, as was shown in Chapter 2, wealth without practical limit is necessary for the achievement of values in the physical world on the scale made possible and required by man’s possession of reason.²⁵ Asceticism is thus simply a doctrine of the negation of human values and human life.

In the last three decades, a powerful new opposition to economic progress has developed. This opposition emanates from the so-called ecology or environmental movement. (In what follows, I use the expressions “ecology doctrine” and “environmentalism,” and “ecologists” and “environmentalists,” interchangeably.) This movement has achieved such a degree of influence that it presently seems on the verge of actually being able to stop further economic progress by means of the enactment of its program into law.

Such a threat cannot be ignored. Indeed, there is no point in explaining how the division of labor makes possible economic progress, and the dependency of the division of labor on capitalism, when the value of economic progress itself has been called into question in this way. Thus, even though it is in the nature of a digression, the doctrines of the environmental movement, and their refutation, must be the subject of the remainder of this chapter.

2. The Claims of the Environmental Movement and Its Pathology of Fear and Hatred

The essential, all-encompassing doctrine of the environmental movement is that the continuation of economic progress is both *impossible and dangerous*. Insofar as it claims the impossibility of the continuation of economic progress, the movement offers nothing more than a repetition of the claims of conservationism. Indeed, it can be considered as having fully absorbed the conservation movement, with conservationism now standing merely as an aspect of environmentalism.

The argument against the possibility of economic progress continuing is, of course, based on the failure to grasp the physical nature of the world and the progressive nature of man. It should not be necessary to dwell further on this aspect of the ecology doctrine, because it has already been thoroughly refuted in Part A of this chapter. There it was shown that the problem of natural resources is strictly one of making a greater fraction of nature’s virtually infinite endowment accessible and economically useable. This in turn was shown to be accomplished to the degree that man gains understanding of and power over nature through scientific and technological progress and correspondingly improved capital equipment.²⁶

The Actual Nature of Industrial Civilization

Before considering the specific claims the environmental movement makes concerning the alleged dangers of economic progress, it is vital to recognize the enormous contribution that the essential vehicle of economic progress, namely, *industrial civilization*, has made to human life and well-being since its birth over two centuries ago in the Industrial Revolution.

Industrial civilization has radically increased human life expectancy: from about thirty years in the mid-eighteenth century to about seventy-five years today. In the twentieth century, in the United States, it has increased life expectancy from about forty-six years in 1900 to the present seventy-five years. The enormous contribution of industrial civilization to human life is further illustrated by the fact that the average newborn American child has a greater chance of living to age sixty-five than the

average newborn child of a nonindustrial society has of living to age five. These marvelous results have come about because of an ever improving supply of food, clothing, shelter, medical care, and all the conveniences of life, and the progressive reduction in human fatigue and exhaustion. All of this has taken place on a foundation of science, technology, and capitalism, which have made possible the continuous development and introduction of new and improved products and more efficient methods of production.

In the last two centuries, loyalty to the values of science, technology, and capitalism has enabled man in the industrialized countries of the Western world to put an end to famines and plagues, and to eliminate the once dread diseases of cholera, diphtheria, smallpox, tuberculosis, and typhoid fever, among others. Famine has been ended, because industrial civilization has produced the greatest abundance and variety of food in the history of the world, and has created the storage and transportation systems required to bring it to everyone. This same industrial civilization has produced the greatest abundance of clothing and shoes, and of housing, in the history of the world. And while some people in the industrialized countries may be hungry or homeless (almost always as the result of destructive government policies), it is certain that no one in the industrialized countries needs to be hungry or homeless.²⁷ Industrial civilization has also produced the iron and steel pipe, the chemical purification and pumping systems, and the boilers, that enable everyone to have instant access to safe drinking water, hot or cold, every minute of the day. It has produced the sewage systems and the automobiles that have removed the filth of human and animal waste from the streets of cities and towns. It has produced the vaccines, anesthetics, antibiotics, and all the other "wonder drugs" of modern times, along with all kinds of new and improved diagnostic and surgical equipment. It is such accomplishments in the foundations of public health and in medicine, along with improved nutrition, clothing, and shelter, that have put an end to plagues and radically reduced the incidence of almost every type of disease.

As the result of industrial civilization, not only do billions more people survive, but in the advanced countries they do so on a level far exceeding that of kings and emperors in all previous ages—on a level that just a few generations ago would have been regarded as possible only in a world of science fiction. With the turn of a key, the push of a pedal, and the touch of a steering wheel, they drive along highways in wondrous machines at sixty miles an hour. With the flick of a switch, they light a room in the middle of darkness. With the touch of a button, they watch events taking place ten thousand miles away. With the touch of a few other buttons, they talk to other

people across town or across the world. They even fly through the air at six hundred miles per hour, forty thousand feet up, watching movies and sipping martinis in air-conditioned comfort as they do so. In the United States, most people can have all this, and spacious homes or apartments, carpeted and fully furnished, with indoor plumbing, central heating, air conditioning, refrigerators, freezers, and gas or electric stoves, and also personal libraries of hundreds of books, records, compact disks, and tape recordings; they can have all this, as well as long life and good health—as the result of working forty hours a week.

The achievement of this marvelous state of affairs has been made possible by the use of ever improved machinery and equipment, which has been the focal point of scientific and technological progress.²⁸ The use of this ever improved machinery and equipment is what has enabled human beings to accomplish ever greater results with the application of less and less muscular exertion.

Now inseparably connected with the use of ever improved machinery and equipment has been the increasing use of *man-made power*, which is the distinguishing characteristic of industrial civilization and of the Industrial Revolution, which marked its beginning. To the relatively feeble muscles of draft animals and the still more feeble muscles of human beings, and to the relatively small amounts of useable power available from nature in the form of wind and falling water, industrial civilization has added man-made power. It did so first in the form of steam generated from the combustion of coal, and later in the form of internal combustion based on petroleum, and electric power based on the burning of any fossil fuel or on atomic energy.

This man-made power, and the energy released by its use, is an equally essential basis of all of the economic improvements achieved over the last two hundred years. It is what enables us to use the improved machines and equipment and is indispensable to our ability to produce the improved machines and equipment in the first place. Its application is what enables us human beings to accomplish with our arms and hands, in merely pushing the buttons and pulling the levers of machines, the amazing productive results we do accomplish. To the feeble powers of our arms and hands is added the enormously greater power released by energy in the form of steam, internal combustion, electricity, or radiation. In this way, energy use, the productivity of labor, and the standard of living are inseparably connected, with the two last entirely dependent on the first.

Thus, it is not surprising, for example, that the United States enjoys the world's highest standard of living. This is a direct result of the fact that the United States has the world's highest energy consumption per capita. The United States, more than any other country, is the country where

intelligent human beings have arranged for motor-driven machinery to accomplish results for them. All further substantial increases in the productivity of labor and standard of living, both here in the United States and across the world, will be equally dependent on man-made power and the growing use of energy it makes possible. Our ability to accomplish more and more with the same limited muscular powers of our limbs will depend entirely on our ability to augment them further and further with the aid of still more such energy.

So little are these elementary facts understood that a thoroughly perverted concept of economic efficiency has come into vogue, a concept whose actual meaning is the precise opposite of economic efficiency. Economic efficiency centers on the ability of human beings to reduce the quantity of labor they need to expend per unit of output and thus to be able to produce more and more while expending the same or a smaller amount of labor. This, of course, requires the growing use of energy per capita, as I have just explained. Nevertheless, increasingly the practice today is to view economic efficiency as centering on how little energy can be consumed per unit of output, which, of course, necessarily implies an increasing need for human labor per unit of output. For example, a front-page article in *The New York Times*, of February 9, 1991, was headlined “Bush’s Energy Plan Emphasizes Gains in Output over Efficiency.” Although the headline meant to refer specifically to the output of energy, the article’s actual position reduces to the absurdity the headline suggests, namely, that increases in the overall output of goods produced by the same amount of human labor are a contradiction of efficiency, for any such increase in production requires the greater production and use of energy per capita, which the article characterizes as inefficient. Along the same lines, a later headline in the same newspaper read “Bad News: Fuel Is Cheap.”²⁹ Later discussion will make clear that the perversion of the concept of efficiency is philosophically consistent with the environmental movement’s most fundamental values.

Now not only does the environmental or ecology movement respond to the marvelous accomplishments of industrial civilization with all of the sensibilities one might expect from a dead log, but in virtually every respect, it represents an attack on industrial civilization, on the values of science, technology, and capitalism on which that civilization rests, and on all of its material fruits, from air conditioners and automobiles to television sets and X-ray machines. The environmental movement is, as Ayn Rand so aptly characterized it, “the Anti-Industrial Revolution.”³⁰

Consistent with what I said earlier in connection with

the values of capitalism, none of the preceding is to say that life in the modern world is without serious problems, especially in many of today’s large cities.³¹ It is to say, however, that the problems are not the result of economic progress, capitalism, technology, science, or human reason. On the contrary, they are the result precisely of the absence of these values. The solution to every problem, from crime to unemployment is a combination of one or more of these essential attributes of industrial civilization. Thus, for example, if rent control destroys the quality of housing in cities, if minimum-wage and pro-union legislation cause unemployment, if inflation and confiscatory taxation cause capital decumulation and economic decline, if acceptance of the doctrine of determinism stops the punishment of criminals—on the grounds that they could not help it—and the crime rate soars, if people are sick and seek health, if they are poor and seek to be richer, the solution is not the destruction of industrial civilization. The solution is more of what industrial civilization rests upon. It is economic freedom—capitalism. It is recognition of the power of reason and thus the power of the individual to improve himself. And it is science, technology, and economic progress.

What the solution is not, is environmentalism.

The Environmental Movement’s Dread of Industrial Civilization

The environmental movement is characterized by pathological fear of industrial civilization and of science and technology. It fears the “pollution” of water and air as the result of industrial production and the emission of its by-products. It fears the poisoning of fish, the destruction of rivers and lakes, the “pollution” of entire oceans. It fears “acid rain,” the destruction of the ozone layer, the onset of a new ice age, the contrary onset of global warming and the melting of the polar icecaps and rise of sea levels. It fears the use of pesticides and herbicides out of fear of the food chain being poisoned. It fears the use of chemical preservatives and countless other alleged causes of cancer stemming from the “chemicals” produced by industrial civilization. It fears radiation not only from atomic power plants but also from color television sets, microwave ovens, toasters, electric blankets, and electric power lines. It fears the disposal of atomic wastes, all other toxic wastes, and all nonbiodegradable wastes. It fears landfills and the destruction of wetlands. It fears the destruction of animal and vegetable species that are useless or even hostile to man, and demands the preservation of each and every one. It demands the preservation or re-creation of everything as it is or was, before the arrival of man on the scene, from “old-growth” forests, stretches of prairie, and Arctic and Antarctic wastes to the reintroduction of wolves and bears into

areas from which they had been eliminated.³²

As I wrote elsewhere, as a result of the influence of the environmental movement, increasing numbers of present-day Americans and West Europeans “view science and technology in reality as they used to be humorously depicted in Boris Karloff and Bela Lugosi movies, namely, as frightening ‘experiments’ going on in Frankenstein’s castle. And casting themselves in a real-life role of terrified and angry Transylvanian peasants, they seek to smash such science and technology.”³³ For all practical purposes, the effect of environmentalism has been the creation of a horde of hysterical bumpkins in the midst of modern civilization.

As a leading manifestation of this phenomenon, a growing number of our contemporaries view atomic power as a terrifying death ray, beyond man’s power to use safely. Their fear is such that they refuse to sanction even the establishment of dump sites for atomic wastes. Indeed, as previously mentioned, the government of the state of New York, itself having been overcome by the fears inculcated by the ecology movement, has dismantled the brand-new, fully constructed Shoreham atomic power plant on Long Island, a plant whose power output would have prevented the overloads and brownouts and blackouts that are now a much more real possibility in the New York City area in the years to come. It and the environmentalists seem to be totally unaware of or unconcerned with such likely consequences of the plant’s dismantling as people being trapped in elevators and subways, massive food spoilage, deaths from heat stroke because of lack of air conditioning, and so on, because that plant and its power output will not exist. All that the state government and the environmentalists seem to have been aware of is their *imagining* of a large-scale radiation leak.

In indulging their fear of atomic power, the environmentalists simply disregard all the scientific and engineering safeguards built into atomic power plants in the United States, such as backup systems, automatic shut-down in the event of coolant loss, and containment buildings capable of withstanding the direct crash of a jet liner.³⁴ They ignore such facts as that the worst nuclear accident in American history—that of the Three Mile Island nuclear plant—actually confirmed the safety of atomic power plants in the United States. Totally unlike the more recent case of Chernobyl in the former Soviet Union, there was not a single death, not a single case of radiation overdose to any member of the public in that accident. In addition, according to studies reported in *The New York Times*, the cancer rate among residents in the area around Three Mile Island is no higher than normal and has not risen.³⁵

To be sure, the case of Chernobyl was a genuine

disaster. But this fact is not an indictment of atomic power, still less of modern science and technology in general. It is an indictment only of the incompetence, and indifference to human life, inherent in communism. Under communism (socialism), there is no incentive to supply people with anything they need or want, including safety.³⁶ In addition, under communism (socialism), the ability of the government to prosecute wrongdoing in connection with the use of means of production is necessarily compromised by the very nature of the case, inasmuch as the state itself is the owner of the means of production and therefore is itself the party responsible for any misuse in connection with them. Indeed, any prosecution by the state would have to be a prosecution of its own officials, logically entailing the prosecution of its very highest officials. This is because under the central planning that is an essential characteristic of socialism the highest officials have responsibility for every detail of economic activity. The implicit need to challenge the top leaders, of course, greatly diminishes the likelihood of such prosecutions. Thus under communism, as the result of the lack both of economic and legal incentives to provide safety, industrial accidents of all kinds are commonplace, including airplane and train crashes. This is a good reason for rejecting communism, but certainly not a rational basis for rejecting atomic power and an industrial society.

As indicated, as a result of the influence of the environmental movement, the fears of a growing number of our contemporaries are such that they refuse to sanction not only atomic dump sites but also new dump sites for the disposal of all kinds of more mundane chemicals that result as a by-product of industrial processes, such as sulfuric, hydrochloric, or nitric acid, dioxin, PCBs, and even ordinary lead or mercury. They refuse to do so out of fear of being poisoned by “toxic wastes.” In addition, they stop eating one thing after another, in terror that it too is poisoned—with preservatives, pesticides, “chemicals.” Increasingly, they view every man-made chemical additive to food as though it were a cause of cancer or other dread disease. More and more they turn to “natural” foods, as though millions of years of blind evolution in the selection of food were to be trusted, but the application of science and human intelligence to the improvement of food were not. The fear of “chemicals” is such that a major and once proud chemical company has felt obliged to change its slogan from “Better Things for Better Living Through Chemistry” to, simply, “Better Things for Better Living,” because the very word *chemistry* has become controversial and a source of fear. Increasingly, our contemporaries also fear ordinary mechanical devices, from automobiles and washing machines on down to stepladders, and demand absolute

guarantees of safety in connection with their use. All of these fears are supposedly in response to the allegedly self-destructive tendencies of an industrial society.

Yet in virtually no case has any actual *proof* of danger ever been offered. Indeed, some of the claims immediately show themselves to be absurd on simple logical grounds. For example, it is a contradiction to fear both a new ice age *and* a global warming. Since everything physical in the world is a chemical, it is absurd to fear *chemical* preservatives. Such a fear is tantamount to the fear of preservatives as such and thus fear of the very fact that food does not spoil as rapidly.

Not only is there no proof of danger from industrial civilization and science and technology, but all the proof runs entirely the other way. As I have shown, the actual effect of industrial civilization, science, and technology has been to increase life expectancy by two and a half times since the beginning of the Industrial Revolution and radically to improve human health and well-being. The environmentalists simply ignore all this. In their view, it is outweighed by “air pollution.” This belief is clearly present in the words of Carl Sagan, a leading environmentalist:

The “satanic mills” of England in the early years of the industrial revolution polluted the air and caused an epidemic of respiratory disease. The “pea soup” fogs of London, which provided haunting backdrops to the Sherlock Holmes stories, were deadly domestic and industrial pollution. Today, automobiles add their exhaust fumes, and our cities are plagued by smog—which affects the health, happiness and productivity of the very people generating the pollutants. We’ve also known about acid rain, the pollution of lakes and forests, and the ecological turmoil caused by oil spills. But the prevailing opinion has been—erroneously, in my view—that these penalties to health and environment were more than balanced by the benefits that fossil fuels bring.³⁷

Thus, Sagan has declared that in his view it is erroneous to believe that the progressive and radical increase in life expectancy and in human health and well-being outweigh the ill effects of air pollution. For it is precisely these which are the benefits which fossil fuels have brought. The avoidance of air pollution is allegedly more important.

Interestingly, in presenting the Industrial Revolution as the cause of respiratory disease, Sagan somehow manages to forget the virtually total elimination of tuberculosis and the radical reduction in the frequency of, and mortality resulting from, pneumonia, which has been achieved by industrial civilization. Tuberculosis and pneumonia, of course, were traditionally the leading respiratory diseases. In virtually totally eliminating the one and radically reducing the other, the positive contribution of industrial civilization specifically to respiratory health

overwhelmingly surpasses the negative of any respiratory diseases resulting from industrial civilization. Sagan, of course, does not even bother to specify the nature and extent of such alleged diseases. In his view, in developing industrial civilization, we have gotten ourselves into a “mess.”³⁸

The fear the environmental movement has of industrial civilization leads it to want to destroy industrial civilization. Thus, an essential goal of environmentalism is to block the increase in one source of man-made power after another and ultimately to roll back the production of man-made power to the point of virtual nonexistence, thereby undoing the Industrial Revolution and returning the world to the economic Dark Ages. There is to be no atomic power. According to the environmentalists, it represents the death ray. There is also to be no power based on fossil fuels. According to the environmentalists, it causes “air pollution,” and now global warming, and must therefore be given up. There is not even to be significant hydropower. According to the environmentalists, the building of the necessary dams destroys intrinsically valuable wildlife habitat.

Only three things are to be permitted as sources of energy, according to the environmentalists. Two of them, “solar power” and power from windmills, are, as far as can be seen, utterly impracticable as significant sources of energy. (If, somehow, they became practicable, the environmentalists would undoubtedly find grounds for attacking them: they would denounce them for such things as the massive reflection of light from thousands or tens of thousands of acres filled with solar panels, or for maiming and killing birds with their propellers.) The third allowable source of energy, “conservation,” is a contradiction in terms. Conservation is *not* a source of energy. Its actual meaning is simply using less. Conservation is a source of energy for one use only at the price of deprivation of energy use somewhere else.³⁹

The environmentalists’ campaign against energy calls to mind the image of a boa constrictor entwining itself about the body of its victim and slowly squeezing the life out of him. There can be no other result for the economic system of the industrialized world but enfeeblement and ultimately death if its supplies of energy are progressively choked off.

The Toxicity of Environmentalism and the Alleged Intrinsic Value of Nature

The environmental movement’s blindness to the value of industrial civilization is matched only by the blindness of the general public toward the nature of the environmental movement’s own actual values. Those values explain the movement’s hostility to industrial civilization, including its perversion of the concept of efficiency.

They are not known to most people, because the environmental movement has succeeded in focusing the public's attention on absolutely trivial, indeed, nonexistent dangers, and away from the enormous actual danger it itself represents.

Thus, not so long ago, as a result of the influence of the environmental movement, a popular imported mineral water was removed from the market because tests showed that samples of it contained thirty-five parts per billion of benzene. Although this was an amount so small that not many years ago it would have been impossible even to detect, it was assumed that considerations of public health required withdrawal of the product.

Such a case, of course, is not unusual nowadays. The presence of parts per billion of a toxic substance is routinely extrapolated into being regarded as a cause of human deaths. And whenever the number of projected deaths exceeds one in a million (or less), environmentalists demand that the government remove the offending pesticide, preservative, or other alleged bearer of toxic pollution from the market. They do so, even though a level of risk of one in a million is one-third as great as that of an airplane falling from the sky on one's home.

While it is not necessary to question the good intentions and sincerity of the overwhelming majority of the rank-and-file members of the environmental or ecology movement, it is vital that the public realize that in this movement itself, which is so widely regarded as noble and lofty, can be found more than a little evidence of the most profound toxicity—evidence provided by leaders of the movement themselves, and in the clearest possible terms. Consider, for example, the following quotation from David M. Graber, a research biologist with the National Park Service, in his prominently featured *Los Angeles Times* book review of Bill McKibben's *The End of Nature*:

This [man's "remaking the earth by degrees"] makes what is happening no less tragic for those of us who value wildness for its own sake, not for what value it confers upon mankind. I, for one, cannot wish upon either my children or the rest of Earth's biota a tame planet, be it monstrous or—however unlikely—benign. McKibben is a biocentrist, and so am I. We are not interested in the utility of a particular species or free-flowing river, or ecosystem, to mankind. They have intrinsic value, more value—to me—than another human body, or a billion of them.

Human happiness, and certainly human fecundity, are not as important as a wild and healthy planet. I know social scientists who remind me that people are part of nature, but it isn't true. Somewhere along the line—at about a billion years ago, maybe half that—we quit the contract and became a cancer. We have become a plague upon ourselves and upon the Earth.

It is cosmically unlikely that the developed world will

choose to end its orgy of fossil-energy consumption, and the Third World its suicidal consumption of landscape. Until such time as *Homo sapiens* should decide to rejoin nature, some of us can only hope for the right virus to come along.⁴⁰

While Mr. Graber openly wishes for the death of a billion people, Mr. McKibben, the author he reviewed, quotes with approval John Muir's benediction to alligators, describing it as a "good epigram" for his own, "humble approach": "Honorable representatives of the great saurians of older creation, may you long enjoy your lilies and rushes, and be blessed now and then with a mouthful of terror-stricken man by way of a dainty!"⁴¹

Such statements represent pure, unadulterated poison. They express ideas and wishes that, if acted upon, would mean terror and death for enormous numbers of human beings.

These statements, and others like them, are made by prominent members of the environmental movement.⁴² The significance of such statements cannot be diminished by ascribing them only to a small fringe of the environmental movement. Indeed, even if such views were indicative of the thinking only of 5 or 10 percent of the members of the environmental movement—the "deep ecology," Earth First! wing—they would represent toxicity in the environmental movement as a whole not at the level of parts per billion or even parts per million, but at the level of *parts per hundred*, which, of course, is an enormously higher level of toxicity than what is deemed to constitute a danger to human life in virtually every other case in which deadly poison is present.

But the toxicity level of the environmental movement as a whole is much greater even than parts per hundred. It is certainly at least at the level of *several parts per ten*. This is obvious from the fact that the mainstream of the environmental movement makes no fundamental or significant criticisms of the likes of Messrs. Graber and McKibben. Indeed, John Muir, whose wish for alligators to "be blessed now and then with a mouthful of terror-stricken man by way of a dainty" McKibben approvingly quotes, was the founder of the *Sierra Club*, which is proud to acknowledge that fact. The *Sierra Club*, of course, is the leading environmental organization and is supposedly the most respectable of them.

There is something much more important than the *Sierra Club's* genealogy, however—something which provides an explanation in terms of *basic principle* of why the mainstream of the ecology movement does not attack what might be thought to be merely its fringe. This is a fundamental philosophical premise which the mainstream of the movement shares with the alleged fringe and which logically implies hatred for man and his achievements. Namely, the premise that *nature possesses intrinsic value*—that is, that nature is valuable in and of

itself, apart from all contribution to human life and well-being.

The antihuman premise of nature's intrinsic value goes back, in the Western world, as far as St. Francis of Assisi, who believed in the equality of all living creatures: man, cattle, birds, fish, and reptiles. Indeed, precisely on the basis of this philosophical affinity, and at the wish of the mainstream of the ecology movement, St. Francis of Assisi has been officially declared the patron saint of ecology by the Roman Catholic church.

The premise of nature's intrinsic value extends to an alleged intrinsic value of forests, rivers, canyons, and hillsides—to everything and anything that is not man. Its influence is present in the Congress of the United States, in such statements as that made by Representative Morris Udall of Arizona: to wit, that a frozen, barren desert in Northern Alaska, where substantial oil deposits appear to exist, is "a sacred place" that should never be given over to oil rigs and pipelines. It is present in the supporting statement of a representative of the Wilderness Society that "There is a need to protect the land not just for wildlife and human recreation, but just to have it there."⁴³ It has, of course, also been present in the sacrifice of the interests of human beings for the sake of snail darters and spotted owls.

The idea of nature's intrinsic value inexorably implies a desire to destroy man and his works because it implies a perception of man *as the systematic destroyer of the good, and thus as the systematic doer of evil*. Just as man perceives coyotes, wolves, and rattlesnakes as evil because they regularly destroy the cattle and sheep he values as sources of food and clothing, so on the premise of nature's intrinsic value, the environmentalists view man as evil, because, in the pursuit of his well-being, man systematically destroys the wildlife, jungles, and rock formations that the environmentalists hold to be intrinsically valuable. Indeed, from the perspective of such alleged intrinsic values of nature, the degree of man's alleged destructiveness and evil is directly in proportion to his loyalty to his essential nature. Man is the rational being. It is his application of his reason in the form of science, technology, and an industrial civilization that enables him to act on nature on the enormous scale on which he now does. Thus, it is his possession and use of reason—manifested in his technology and industry—for which he is hated.

Indeed, the doctrine of intrinsic value implies that man is to regard himself as profaning the sacredness of nature by virtue of his very existence, because with every breath he draws and every step he takes he cannot help but disturb something or other of alleged intrinsic value. Thus, if man is not to extinguish his existence altogether, he is obliged by the doctrine of intrinsic value to mini-

mize his existence by minimizing his impact on the rest of the world, and to feel guilty for every action he takes in support of his existence.

The doctrine of intrinsic value is itself, of course, only a rationalization for a preexisting hatred of man. It is invoked not because one attaches any actual value to what is alleged to have intrinsic value, but simply to serve as a pretext for denying values to man. For example, caribou feed upon vegetation, wolves eat caribou, and microbes attack wolves. Each of these, the vegetation, the caribou, the wolves, and the microbes, is alleged by the environmentalists to possess intrinsic value. Yet absolutely no course of action is indicated for man. Should man act to protect the intrinsic value of the vegetation from destruction by the caribou? Should he act to protect the intrinsic value of the caribou from destruction by the wolves? Should he act to protect the intrinsic value of the wolves from destruction by the microbes? Even though each of these alleged intrinsic values is at stake, man is not called upon to do anything. When does the doctrine of intrinsic value serve as a guide to what man should do? Only when *man* comes to attach value to something. Then it is invoked to deny him the value he seeks. For example, the intrinsic value of the vegetation et al. is invoked as a guide to man's action only when there is something man wants, such as oil, and then, as in the case of Northern Alaska, its invocation serves to stop him from having it. In other words, the doctrine of intrinsic value is nothing but a doctrine of the negation of human values. It is pure nihilism.

It should be realized that it is logically implicit in what has just been said that to establish a public office such as that proposed in California, of "Environmental Advocate," would be tantamount to establishing an office of Negator of Human Valuation. The work of such an office would be to stop man from achieving his values for no other reason than that he was man and wanted to achieve them.

Of course, the environmental movement is not pure poison. Very few people would listen to it if it were. As I have said, it is poisonous only at the level of several parts per ten. Mixed in with the poison and overlaying it as a kind of sugarcoating is the advocacy of many measures which have the avowed purpose of promoting human life and well-being, and among these, some that, considered in isolation, might even achieve that purpose. The problem is that the mixture is poisonous. And thus, when one swallows environmentalism, one inescapably swallows poison.

Given the underlying nihilism of the movement, it is certainly not possible to accept at face value any of the claims it makes of seeking to improve human life and

well-being, especially when following its recommendations would impose on people great deprivation or cost. Indeed, nothing could be more absurd or dangerous than to take advice on how to improve one's life and well-being from those who wish one dead and whose satisfaction comes from human terror, which, of course, as I have shown, is precisely what is wished in the environmental movement—openly and on principle. This conclusion, it must be stressed, applies irrespective of the scientific or academic credentials of an individual. If an alleged scientific expert believes in the intrinsic value of nature, then to seek his advice is equivalent to seeking the advice of a medical doctor who was on the side of the germs rather than the patient, if such a thing can be imagined. Obviously, congressional committees taking testimony from alleged expert witnesses on the subject of proposed environmental legislation need to be aware of this fact and never to forget it.

Not surprisingly, in virtually every significant case, the claims made by the environmentalists have turned out to be false or simply absurd.

The Alleged Pollution of Water and Air and Destruction of Species

The ecologists claim that economic progress and the industrial civilization that underlies it have been responsible for polluting the water and air and wantonly destroying animal and vegetable species, thereby endangering human life. To answer the ecologists' claims in these areas, it is only necessary to recall a few facts that are known to everyone.

First, as concerns the relationship between industrialization and water quality: it is obvious that the actual safety of drinking water is in direct proportion to a country's degree of economic advancement. One can safely drink the water virtually everywhere in the United States. One can do so in the major cities of Western Europe. But in travelling to poorer areas, such as Mexico, most of the rest of Latin America, and most of Asia and Africa, it is necessary to take precautions. (The recent cholera epidemic in Peru, with its chemically untreated, "natural" water supply provides a tragic testimony to the truth of the preceding statements.) Certainly, if one travels in the African or Vietnamese jungles, or even in the Canadian wilderness, one had better boil the water or use purification tablets. Even in a beautiful blue Canadian lake—the kind for which environmentalist posters used to depict an American Indian shedding a tear—there can be dead, decaying animals emitting morbid germs into the water one may happen to drink. The safety of water supplies obviously depends on chemical purification plants, pipelines, and pumping stations—in a word, on modern industry. While some rivers, lakes, and streams in the

industrialized countries may be dirtier today than in the past, supplies of safe drinking water have never been greater, thanks to modern industry. (And, no doubt, many or most of the presently dirty bodies of water too would be clean and safe, if they were made subject to private property rights. In that case, individuals would have the incentive to make them clean and safe by being able to charge for water and such benefits as fishing rights.)

Second, as concerns the relationship between industrialization and air quality, the obvious fact is that although air quality in large towns and cities is poorer than that in the open country, and always has been, it is far better today than in the past—precisely because of economic progress. Before the advent of modern industry, the open streets served as sewers. In addition, in any large town or city, a heavy concentration of horses created an enormous pollution problem from the dropping of vast quantities of manure and urine. The development of the modern iron and steel industry eliminated the sewage problem with low-cost iron and steel pipe; the development of the automobile industry eliminated the pollution from horses. Central heating, air conditioning, indoor plumbing, and modern methods of ventilation have made further major contributions to improving the quality of the air in which people live and work.

And although in the earlier years of the Industrial Revolution the process of economic improvement was accompanied by coal dust in towns and cities (which people willingly accepted as the by-product of not having to freeze and of being able to have all the other advantages of an industrial society), subsequent advances, in the form of electricity and natural gas, have radically reduced this problem. The substitution of atomic power plants for coal and oil-fired plants would make a further major contribution to air quality, because they emit no particulate matter of any kind into the atmosphere. Atomic power, however, is the form of power most hated by the environmentalists.⁴⁴ As shown previously, the virtual elimination of tuberculosis and the radical reduction in the frequency of, and mortality rate resulting from, other respiratory diseases, such as pneumonia, provide further eloquent testimony to the actual contribution of industrial civilization to air quality.

Third, as concerns man's alleged wanton destruction of other species: man is responsible for the existence of many species of animals and plants in their present numbers and varieties. For example, man is responsible for the existence of the overwhelming majority of the cattle, sheep, hogs, chickens, goats, horses, and cats and dogs that are alive, and for the existence of most of the specific breeds in which they exist. There would certainly be no such things as Holstein cattle, thoroughbred racehorses, miniature schnauzers, toy poodles, or Persian

cats, in the absence of man. The population of all varieties of domestic animals would be radically reduced without the existence of man to feed them, promote their health, and protect them from their natural enemies. In the same way, man is responsible for the fact that grain, vegetables, flowers, and grass grow where otherwise there would be only weeds. Man is responsible for the existence of all manner of specific strains of plant life, from American Beauty roses to varieties of zucchini.

Furthermore, as we have seen, despite the misconceptions spawned by conservationism and the ecology doctrine, where forest land is privately owned, man is also responsible for the existence of many trees and forests, which the profit motive leads him to regard as a long-term crop.⁴⁵ In addition, of course, man also plants trees as objects of beauty to enhance his surroundings. Practically all of the trees in many portions of Southern California and other arid areas were planted and are maintained by man for just this reason.

Man is clearly not the destroyer of species. He enormously promotes the existence of those species that are of benefit to him. He seeks to destroy only those species that are harmful to him, including those that are harmful to the species whose existence he tries to promote. Thus, he seeks to extirpate such species as the smallpox virus, rats, fleas, rattlesnakes, coyotes, wolves, and mountain lions.

Sometimes, of course, cases arise in which his activity threatens the existence of species that are not hostile and that have been useful to him, such as the American buffalo and, nowadays, certain varieties of whales. In these cases, the species are not domesticated and raised commercially because the usefulness of the animal is not great enough to justify the expense involved.⁴⁶

It might be of some value if a few members of every species could be preserved as objects of study or curiosity and perhaps as a future source of genes for use in genetic engineering. From this point of view, it would be a welcome event if the story line of some low-budget films became a reality and a scientific expedition were to come upon a preserve of dinosaurs somewhere. Those who consider such objectives important, and there certainly appears to be no lack of such people, are free to raise money to establish wildlife preserves. Nevertheless, from a practical point of view, it is obvious that man's life would simply not be significantly affected by the passing of such species as the buffalo or the endangered whales. The mere fact that the loss of a species may be irreplaceable from a genetic point of view, and that at some point in the future it might conceivably be regretted for this reason, is not a logical basis for arguing that it must not be allowed to occur. If this line of argument were accepted, people could never clean their garages or

throw anything away, for who knows, the clutter might contain a letter from George Washington or a winning lottery ticket. Furthermore, the ecology movement, ironically enough, strongly opposes any human use to which such an enlarged future gene pool might be put: it is totally opposed to genetic engineering. The sense of moral imperative it projects in seeking not to permit the loss of any species derives from its mistaken notion that species possess intrinsic value.

The disappearance of species has been going on since the beginning of life on earth. It appears to be no more rapid now than at any other time. Furthermore, to whatever extent it occurs as the result of human activity, it is still simply part of the process of nature. Man himself is part of nature. Any species that he may destroy in the course of his activities cannot in reason be regarded any differently from the countless species destroyed by any other natural process.

If one wishes to judge matters from an ethical perspective, the only valid perspective is that of man himself—that is, a perspective which takes for granted the supreme value of human life and well-being and man's right to do everything in his power to promote his life and well-being. From this point of view, one cannot regard man's activities in relation to nature with anything but awe and admiration. In the territories embraced by modern Western civilization, he has not only succeeded in these activities, but succeeded with surpassing brilliance. For he has transformed his environment to promote his survival and well-being. He has transformed enormous areas that were originally hostile or at best indifferent to his survival into virtual gardens—into thriving areas of agriculture, industry, and commerce. In so doing, he has changed the balance of nature radically in his favor.

In view of these facts, the environmentalists' claims that the effect of man's productive activities in an industrial society on water, air, and species represents any kind of danger to human life and well-being are patently absurd. All of the isolated negatives the environmentalists point to, such as smog in some cities, or dirty rivers, lakes, or beaches in various places, have occurred in the context of the most radical improvements in human life, health, and well-being, including the most radical improvements in the quality of the water people drink and otherwise use, in the quality of the air they live and work in, and in the whole balance of nature. Nevertheless, the environmentalists proceed as though problems of filth emanated from industrial civilization, as though filth were not the all-pervasive condition of human life in preindustrial societies, and as though industrial civilization represented a decline from more healthful conditions of the past. If it is filth and squalor one wants to complain about, one should go to virtually any of the

countries of the so-called third world, which are not industrialized. There one will find filth and squalor—"pollution"—of the worst kind: human excrement and, indeed, human corpses floating downstream and contaminating the rivers through which they pass.

Moreover, as previously indicated, what would overcome most of the isolated negatives in the industrial societies, apart from the wider use of atomic power, would be the extension of private ownership of the means of production, especially of land and natural resources. The incentive of private owners is to use their property in ways that maximize its long-run value and wherever possible, to improve their property. Consistent with this fact, ways should be sought for extending the principle of private ownership to lakes, rivers, beaches, and even to portions of the ocean. Privately owned lakes, rivers, and beaches, would almost certainly be clean lakes, rivers, and beaches. Privately owned, electronically fenced ocean ranches would guarantee abundant supplies of almost everything useful that is found in or beneath the sea. Certainly, the vast landholdings of the U.S. government in the Western states and in Alaska should be privatized.

Of course, what leads the environmentalists to make their claims concerning water and air pollution and the destruction of species is not any actual concern with human life and well-being. Human life and well-being, it cannot be repeated too often, are not their standard of what is good; instead, it is the alleged intrinsic values found in nature.

The Alleged Threat from Toxic Chemicals, Including Acid Rain and Ozone Depletion

Almost all of the other claims of the environmentalists, which for the most part are more recent, do not fare any better than their claims concerning water and air pollution and the destruction of species. In virtually every case, they too have turned out to be false or simply absurd.

Consider, for example, the recent case of Alar, a chemical spray used for many years on apples in order to preserve their color and freshness. Here, it turned out that even if the environmentalists' claims had actually been true, that the use of Alar would result in 4.2 deaths per million over a 70-year lifetime, all that would have been signified was that eating apples sprayed with Alar would then have been less dangerous than driving to the supermarket to buy the apples!

Consider: 4.2 deaths per million over a 70-year period means that in any one year in the United States, with its population of roughly 250 million people, approximately 15 deaths would be attributable to Alar! This is the result obtained by multiplying 4.2 per million times 250 mil-

lion and then dividing by 70. In the same one-year period, approximately 50,000 deaths occur in motor vehicle accidents in the United States, most of them within a few miles of the victims' homes, and undoubtedly far more than 15 of them on trips to or from supermarkets. Nevertheless, because of irresponsible, sensationalist newspaper and television reporting of the ecologists' claims concerning Alar, a panic ensued, followed by a plunge in the sale of apples, the financial ruin of an untold number of apple growers, and the virtual disappearance of Alar.

Before the panic over Alar, there was the panic over asbestos. According to *Forbes* magazine, it turns out that in the forms in which it is normally used in the United States, asbestos is one-third as likely to be the cause of death as being struck by lightning.⁴⁷

Then there is the alleged damage to lakes and forests caused by acid rain. While the phenomenon of acid rain certainly exists (largely as the result of governmental insistence on the construction of smokestacks two hundred feet or more tall), it turns out, according to *Policy Review*, that the acidification of the lakes and surrounding forests has been the result not of acid rain, but of the cessation of logging operations in the affected areas and thus the absence of the alkaline runoff produced by such operations. This runoff had made naturally acidic lakes and forests nonacidic for a few generations.⁴⁸ Furthermore, according to the final report of the U.S. government's National Acid Precipitation Assessment Program, the direct major cause of acidification appears to be simply one hundred fifty million tons a year of bird droppings.⁴⁹

Besides these cases, there were the respective hysterias over dioxin in the ground at Times Beach, Missouri; TCE in the drinking water of Woburn, Massachusetts; the chemicals in Love Canal, in New York; and radiation at Three Mile Island, in Pennsylvania. (The last has already been shown to be groundless.) According to Professor Bruce Ames, one of the world's leading experts on cancer, the amount of dioxin that anyone would have absorbed in Times Beach was far less than the amount required to do any harm and, indeed, the actual harm to Times Beach residents from dioxin was less than that of drinking a glass of beer.⁵⁰ (The Environmental Protection Agency itself subsequently reduced its estimate of the danger from dioxin by a factor of fifteen-sixteenths.⁵¹) In the case of Woburn, according to Ames, it turned out that the cluster of leukemia cases which occurred there was statistically random and that the drinking water there was actually above the national average in safety, and not, as had been claimed, the cause of the leukemia cases.⁵² In the case of Love Canal, Ames reports, it turned out upon investigation that the cancer rate among the former residents was no higher than average.⁵³ (It is necessary to use the phrase "former residents" because

the town lost most of its population in the panic and forced evacuation caused by the environmentalists' claims.) Overall, Ames writes, "There is no convincing evidence from epidemiology or toxicology that pollution is a significant source of birth defects and cancer. . . . the epidemiologic studies of Love Canal, dioxin in Agent Orange, Contra Costa County refineries, Silicon Valley, Woburn, and the use of DDT provide no convincing evidence that pollution was the cause of human harm in any of these well-publicized exposures."⁵⁴ The reason is that the amount of actual exposure was simply far too small to be harmful.

Before these hysterias, there were allegations about the death of Lake Erie and mercury poisoning in tuna fish. All along, Lake Erie has been very much alive and was even producing near record quantities of fish at the very time its death was being announced. The mercury in the tuna fish was the result of the natural presence of mercury in sea water; and evidence provided by museums showed that similar levels of mercury had been present in tuna fish since prehistoric times.

And now, in yet another overthrow of the environmentalists' claims, a noted climatologist, Professor Robert Pease, has shown that it is impossible for chlorofluorocarbons (CFCs) to destroy large quantities of ozone in the stratosphere because relatively few of them are even capable of reaching the stratosphere in the first place. He also shows that the celebrated ozone "hole" over Antarctica every fall is a phenomenon of nature, probably in existence since long before CFCs were invented, and results largely from the fact that during the long Antarctic night ultraviolet sunlight is not present to create fresh ozone.⁵⁵

The Dishonesty of the Environmentalists' Claims

The reason that one after another of the environmentalists' claims turn out to be proven wrong is that they are made without any regard for truth in the first place. In making their claims, the environmentalists reach for whatever is at hand that will serve to frighten people, make them lose confidence in science and technology, and, ultimately, lead them to deliver themselves up to the environmentalists' tender mercies. The claims rest on unsupported conjectures and wild leaps of imagination from scintillas of fact to arbitrary conclusions, by means of evasion and the drawing of invalid inferences. It is out and out evasion and invalid inference to leap from findings about the effects of feeding rats or mice dosages the equivalent of a hundred or more times what any human being would ever ingest, and then draw inferences about the effects on people of consuming normal quantities. Fears of parts per billion of this or that chemical causing single-digit deaths per million do not rest on science, but on imagination. Such claims are based neither on exper-

iments nor on the concept of causality.

No one ever has observed, or can or will observe, such a thing as two groups of a million people identical in all respects except that over a 70-year period the members of one of the groups consume apples sprayed with Alar, while the members of the other group do not, and then 4.2 members of the first group die. The process by which such a conclusion is reached, and its degree of actual scientific seriousness, is essentially the same as that of a college students' bull session, which consists of practically nothing but arbitrary assumptions, manipulations, guesses, and plain hot air. In such a session, one might start with the known consequences of a quarter-ton safe falling ten stories onto the head of an unfortunate passerby below, and from there go on to speculate about the conceivable effects in a million cases of other passersby happening to drop from their hand or mouth an M&M or a peanut on their shoe, and come to the conclusion that 4.2 of them will die.

Furthermore, as indicated, in contrast to the procedures of a bull session, reason and actual science establish causes, which, in their nature, are *universal*. When, for example, genuine causes of death, such as arsenic, strychnine, or bullets, attack vital organs of the human body, death is absolutely certain to result in *all but* a handful of cases per million. When something is in fact the cause of some effect, it is *so in each and every case* in which specified conditions prevail, and fails to be so only in cases in which the specified conditions are not present, such as a person's having built up a tolerance to poison or wearing a bulletproof vest. Such claims as a thousand different things each causing cancer in a handful of cases are proof of nothing but that the actual causes are not yet known—and, beyond that, an indication of the breakdown of the epistemology of contemporary science. (This epistemological breakdown, I might add, has radically accelerated since the 1960s, when the government took over most of the scientific research in the United States and began the large-scale financing of statistical studies as a substitute for the discovery of causes.)

In making their claims, the environmentalists willfully ignore such facts as that carcinogens, poisons, and radiation exist in nature. Fully half of the chemicals found in nature are carcinogenic when fed to animals in massive quantities—the same proportion as applies to man-made chemicals when fed in massive quantities. (The cause of the resulting cancers, according to Professor Ames, is actually not the chemicals, either natural or man-made, but the repeated destruction of tissue caused by the massively excessive doses in which the chemicals are fed, such as saccharin being fed to rats in a quantity comparable to humans drinking eight hundred cans of

diet soda a day.⁵⁶) Arsenic, one of the deadliest poisons, is a naturally occurring chemical element. Oleander, one of the most beautiful plants, is also a deadly poison, as are many other plants and herbs. Radium and uranium, with all their radioactivity, are found in nature. Indeed, all of nature is radioactive to some degree. If the environmentalists did not close their eyes to what exists in nature, if they did not associate every negative exclusively with man, if they applied to nature the standards of safety they claim to be necessary in the case of man's activities, *they would have to run in terror from nature*. They would have to use one-half of the world to construct protective containers or barriers against all the allegedly deadly carcinogens, toxins, and radioactive material that constitute the other half of the world.

It would be a profound mistake to dismiss the repeatedly false claims of the environmentalists merely as a case of the little boy who cried wolf. They are a case of the *wolf* crying again and again about alleged dangers to the little boy. The only real danger, of course, is to listen to the wolf.

Direct evidence of the willful dishonesty of the environmental movement comes from one of its leading representatives, Stephen Schneider, who is well-known for his predictions of global catastrophe. In the October 1989 issue of *Discover* magazine, he is quoted (with approval) as follows:

“. . . To do this, we need to get some broad-based support, to capture the public's imagination. That, of course, entails getting loads of media coverage. So we have to offer up scary scenarios, make simplified, dramatic statements, and make little mention of any doubts we may have. This 'double ethical bind' we frequently find ourselves in cannot be solved by any formula. Each of us has to decide what the right balance is between being effective and being honest.”

Thus, in the absence of verification by sources totally independent of the environmental movement and free of its taint, all of its claims of seeking to improve human life and well-being in this or that specific way must be regarded simply as lies, having the actual purpose of inflicting needless deprivation or suffering. In the category of malicious lies fall all of the environmental movement's claims about our having to abandon industrial civilization or any significant part of it in order to cope with the dangers of alleged global warming, ozone depletion, exhaustion of natural resources, or any other alleged danger. Indeed, all claims constituting denunciations of science, technology, or industrial civilization which are advanced in the name of service to human life and well-being are tantamount to claiming that our survival and well-being depend on our abandonment of reason. (Science, technology, and industry are leading products of reason and are inseparable from it.) All such

claims should be taken as nothing but further proof of the environmental movement's hatred of man's nature and man's life, certainly not of any actual significant danger to human life and well-being.

The Alleged Threat of “Global Warming”

Currently, the leading claim of the environmentalists is that of “global warming.” It is alleged that man's economic activities, above all the burning of fossil fuels, are increasing the amount of carbon dioxide in the atmosphere. This will supposedly raise the average mean temperature of the world by several degrees over the next century and will cause a rise in sea levels because of melting ice.

It should be realized that despite the sensationalist claims of James Hansen of NASA, made during the heat wave of the summer of 1988, that global warming was at hand, weather satellites showed no evidence of global warming in the 1980s.⁵⁷ According to *The New York Times*, “Few scientists believe that greenhouse warming can now be detected amid the normal swings of climate.”⁵⁸

If one did not understand its underlying motivation, the environmental movement's resort to the fear of global warming might appear astonishing in view of all the previous fears the movement has professed. These fears, in case anyone has forgotten, have concerned the alleged onset of a *new ice age* as the result of the same industrial development that is now supposed to result in global warming, and the alleged creation of a “nuclear winter” as the result of man's use of atomic explosives.

The words of Paul Ehrlich and his incredible claims in connection with the “greenhouse effect” should be recalled. In the first wave of ecological hysteria, that “scientist” declared:

At the moment we cannot predict what the overall climatic results will be of our using the atmosphere as a garbage dump. We do know that very small changes in either direction in the average temperature of the Earth could be very serious. With a few degrees of cooling, a new ice age might be upon us, with rapid and drastic effects on the agricultural productivity of the temperate regions. With a few degrees of heating, the polar ice caps would melt, perhaps raising ocean levels 250 feet. Gondola to the Empire State Building, anyone?⁵⁹

The 250-foot rise in the sea level projected by Ehrlich as the result of global warming has been scaled back somewhat. According even to McKibben, the “worst case scenario” is now supposed to be 11 feet, by the year 2100, with something less than 7 feet considered more likely.⁶⁰ According to a United Nations panel, it is supposed to be 25.6 inches.⁶¹ (Even this still more limited projected rise did not stop the U.N. panel, allegedly composed of scientists, from calling for an immediate 60

percent reduction in worldwide carbon dioxide emissions to try to prevent it.⁶²)

Perhaps of even greater significance is the continuous and profound distrust of science and technology that the environmental movement displays. The environmental movement maintains that science and technology cannot be relied upon to build a safe atomic power plant, to produce a pesticide that is safe, or even to bake a loaf of bread that is safe, if that loaf of bread contains chemical preservatives. When it comes to global warming, however, it turns out that there is one area in which the environmental movement displays the most breathtaking confidence in the reliability of science and technology, an area in which, until recently, no one—not even the staunchest supporters of science and technology—had ever thought to assert very much confidence at all. The one thing, the environmental movement holds, that science and technology can do so well that we are entitled to have unlimited confidence in them is *forecast the weather*—for the next one hundred years!

It is, after all, supposedly on the basis of a weather forecast that we are being asked to abandon the Industrial Revolution or, as it is euphemistically put, “to radically and profoundly change the way in which we live”—to our enormous material detriment. We are being asked to begin with a curtailment of energy consumption sufficient to achieve a global limitation on carbon dioxide emissions, indeed, a curtailment sufficient to achieve an immediate 60 percent reduction in such emissions. (It is significant, of course, that any global limitation on carbon dioxide emissions, let alone a 60 percent reduction, implies that the economic development, and hence increased energy consumption, of the vast presently backward regions of the world would have to be accomplished at the expense of the equivalently reduced energy consumption of the more advanced countries.)

Very closely connected with the demand for reduced carbon-dioxide emissions and energy consumption is something else that might appear amazing. This concerns prudence and caution. As we have seen, no matter what the assurances of scientists and engineers, based in every detail on the best established laws of physics—about backup systems, fail-safe systems, containment buildings as strong as U-boat pens, defenses in depth, and so on—when it comes to atomic power, the environmental movement is unwilling to gamble on the unborn children of fifty generations hence being exposed to harmful radiation. But on the strength of a weather forecast, it is willing to wreck the economic system of the modern world—to literally throw away industrial civilization. (Any significant limitation on carbon dioxide emissions would be utterly devastating, let alone the enormous immediate reduction urged by that U.N. panel.)

The meaning of this insanity is that industrial civilization is to be wrecked because this is what must be done to *avoid bad weather*. All right, very bad weather. If we destroy the energy base needed to produce and operate the construction equipment required to build strong, well-made, comfortable houses for hundreds of millions of people, we shall be safer from the wind and rain, the environmental movement alleges, than if we retain and enlarge that energy base. If we destroy our capacity to produce and operate refrigerators and air conditioners, we shall be better protected from hot weather than if we retain and enlarge that capacity, the environmental movement claims. If we destroy our capacity to produce and operate tractors and harvesters, to can and freeze food, to build and operate hospitals and produce medicines, we shall secure our food supply and our health better than if we retain and enlarge that capacity, the environmental movement asserts.

There is actually a remarkable new principle implied here, concerning how man can cope with his environment. Instead of our taking action upon nature, as we have always believed we must do, we shall henceforth control the forces of nature more to our advantage by means of our *inaction*. Indeed, if we do not act, no significant threatening forces of nature will arise! The threatening forces of nature are not the product of nature, but of *us!* Thus speaks the environmental movement.

In answer to this insanity, it must be stressed that even if global warming turned out to be a fact, the free citizens of an industrial civilization would have no great difficulty in coping with it—that is, of course, if their ability to use energy and to produce is not crippled by the environmental movement and by government controls otherwise inspired. The seeming difficulties of coping with global warming, or any other large-scale change, arise only when the problem is viewed from the perspective of government central planners.

It would be too great a problem for government bureaucrats to handle (as is the production even of an adequate supply of wheat or nails, as the experience of the whole socialist world has so eloquently shown). But it would certainly not be too great a problem for tens and hundreds of millions of free, thinking individuals living under capitalism to solve. It would be solved by means of each individual being free to decide how best to cope with the particular aspects of global warming that affected him.

Individuals would decide, on the basis of profit-and-loss calculations, what changes they needed to make in their businesses and in their personal lives, in order best to adjust to the situation. They would decide where it was now relatively more desirable to own land, locate farms and businesses, and live and work, and where it was

relatively less desirable, and what new comparative advantages each location had for the production of which goods. Factories, stores, and houses all need replacement sooner or later. In the face of a change in the relative desirability of different locations, the pattern of replacement would be different. Perhaps some replacements would have to be made sooner than otherwise. To be sure, some land values would fall and others would rise. Whatever happened, individuals would respond in a way that minimized their losses and maximized their possible gains.⁶³ The essential thing they would require is the freedom to serve their self-interests by buying land and moving their businesses to the areas rendered relatively more attractive, and the freedom to seek employment and buy or rent housing in those areas.

Given this freedom, the totality of the problem would be overcome. This is because, under capitalism, the actions of the individuals, and the thinking and planning behind those actions, are coordinated and harmonized by the price system (as many former central planners of Eastern Europe and the former Soviet Union have come to learn).⁶⁴ As a result, the problem would be solved in exactly the same way that tens and hundreds of millions of free individuals have solved much greater problems, such as redesigning the economic system to deal with the replacement of the horse by the automobile, the settlement of the American West, and the release of the far greater part of the labor of the economic system from agriculture to industry.

This is not to deny that important problems of adjustment would exist if global warming did in fact come to pass. But whatever they would be, they would all have perfectly workable *solutions*. The most extreme case would be that of the Maldivian Islanders, in the Indian Ocean, all of whose land might disappear under water. The population of the Maldivian Islands is less than two hundred thousand people. In 1940, in a period of a few days, Great Britain was able to evacuate its army of more than three hundred thousand soldiers from the port of Dunkirk, under the threat of enemy gunfire. Surely, over a period of decades, the opportunity for comfortable resettlement could be arranged for the people of the Maldives.

Even the prospective destruction of much of Holland, if it could not be averted by the construction of greater sea walls, could be dealt with by the very simple means of the rest of Europe, and the United States and Canada, extending the freedom of immigration to Dutch citizens. If this were done, then in a relatively short time, the economic losses suffered as the result of physical destruction in Holland would hardly be noticed, and least of all by most of the former Dutchmen.

For densely populated, impoverished countries with

low-lying coastal areas, like Bangladesh and Egypt, the obvious solution is for those countries to sweep away all of the government corruption and underlying irrational laws and customs that stand in the way of large-scale foreign investment and thus of industrialization. This is precisely what needs to be done in these countries in any case, with or without global warming, if their terrible poverty and enormous mortality rates are to be overcome. If they do this, then the physical loss of a portion of their territory will not entail the death of anyone, and, indeed, their standard of living will rapidly improve. If they refuse to do this, then nothing but their own irrationality should be blamed for their suffering. The threat of global warming, if there is really anything to it, should propel them into taking now the actions they should have taken long ago.⁶⁵

Indeed, it would probably turn out that if the necessary adjustments were allowed to be made, global warming, if it actually came, would prove highly beneficial to mankind on net balance. For example, there is evidence suggesting that it would postpone the onset of the next ice age by a thousand years or more and that the higher level of carbon dioxide in the atmosphere, which is supposed to cause the warming process, would be highly beneficial to agriculture by stimulating the growth of vegetation.⁶⁶ Growing seasons too might be extended.⁶⁷

Furthermore, any loss of agricultural land, such as that which is supposed to take place in low-lying areas as the result of higher sea levels, would be far more than compensated for by vast quantities of newly useable land in central Canada and in Russia. In addition, there would be the major contribution made by the preceding clearing of the Amazon and other jungles. (The clearing of these *jungles*—not “tropical rain forests,” as they are euphemistically called nowadays—and the concomitant elimination of their poisonous snakes and other hostile beasts, and replacement with farms and ranches, is an enormous boon from the point of view of human life and well-being.⁶⁸)

Whether global warming comes or not, it is certain that nature itself will sooner or later produce major changes in the climate. To deal with those changes and virtually all other changes arising from whatever cause, man absolutely requires individual freedom, science, and technology. In a word, he requires the industrial civilization constituted by capitalism. What he does not require is the throttling of his ability to act, by the environmental movement. If it really were the case that the average mean temperature of the world would rise a few degrees in the next century as the result of the burning of fossil fuels and of other modern industrial processes, the only appropriate response would be along the lines of being sure that more and better air conditioners were available.

(Similarly, if there were in fact to be some reduction in the ozone layer, the appropriate response, to avoid the additional cases of skin cancer that would allegedly occur from exposure to more intense sunlight, would be to be sure that there were more sunglasses, hats, and sun-tan lotion available.) In absolutely no case would the appropriate response be to seek to throttle and destroy industrial civilization. Primitive man, the ideal of the environmentalists, was incapable of successfully coping with climate changes. Modern man, thanks to industrial civilization and capitalism, *is* capable of successfully coping with climate changes. To do so, it is essential that he ignore the environmentalists and not abandon the intellectual and material heritage that elevates him above primitive man.

Why Economic Activity Necessarily Tends to Improve the Environment

It is important to realize that when the environmentalists talk about destruction of the “environment” as the result of economic activity, their claims are permeated by the doctrine of intrinsic value. Thus, what they actually mean to a very great extent is merely the destruction of alleged intrinsic values in nature such as jungles, deserts, rock formations, and animal species which are either of no value to man or hostile to man. That is their concept of the “environment.” If, in contrast to the environmentalists, one means by “environment” *the surroundings of man*—the external material conditions of human life—then it becomes clear that all of man’s productive activities have the inherent tendency to *improve* his environment, indeed, that that is their essential purpose.

This becomes obvious when one recalls that the entire world physically consists of nothing but chemical elements. These elements are never destroyed. They simply reappear in different combinations, in different proportions, in different places. Apart from what has been lost in a few rockets, the quantity of every chemical element in the world today is the same as it was before the Industrial Revolution. The only difference is that, because of the Industrial Revolution, instead of lying dormant, out of man’s control, the chemical elements have been moved about, as never before, in such a way as to improve human life and well-being. For instance, some part of the world’s iron and copper has been moved from the interior of the earth, where it was useless, to now constitute buildings, bridges, automobiles, and a million and one other things of benefit to human life. Some part of the world’s carbon, oxygen, and hydrogen has been separated from certain compounds and recombined in others, in the process releasing energy to heat and light homes, power industrial machinery, automobiles, air-

planes, ships, and railroad trains, and in countless other ways serve human life. It follows that insofar as man’s environment consists of the chemical elements iron, copper, carbon, oxygen, and hydrogen, and his productive activity makes them useful to himself in these ways, his environment is correspondingly improved.

All that *all* of man’s productive activities fundamentally consist of is the rearrangement of nature-given chemical elements for the purpose of making them stand in a more useful relationship to himself—that is, for the purpose of improving his environment.

Consider further examples. To live, man needs to be able to move his person and his goods from place to place. If an untamed forest stands in his way, such movement is difficult or impossible. It represents an improvement in his environment, therefore, when man moves the chemical elements that constitute some of the trees of the forest somewhere else and lays down the chemical elements brought from somewhere else to constitute a road. It is an improvement in his environment when man builds bridges, digs canals, opens mines, clears land, constructs factories and houses, or does anything else that represents an improvement in the external, material conditions of his life. All of these things represent an improvement in man’s material surroundings—his environment. All of them represent the rearrangement of nature’s elements in a way that makes them stand in a more useful relationship to human life and well-being.

Thus, all of economic activity has as its sole purpose the improvement of the environment—it aims exclusively at the improvement of the external, material conditions of human life. Production and economic activity are precisely the means by which man adapts his environment to himself and thereby improves it.

So much for the environmentalists’ claims about man’s destruction of the environment. Only from the perspective of the alleged intrinsic value of nature and the nonvalue of man, can man’s improvement of his environment be termed destruction of the environment.

The environmentalists’ claims about the impending destruction of the “planet” are entirely the result of the influence of the intrinsic value doctrine. What the environmentalists are actually afraid of is not that the planet or its ability to support human life will be destroyed, but that *the increase in its ability to support human life* will destroy its still extensively existing “wildness.” They cannot bear the thought of the earth becoming fully subject to man’s control, with its jungles and deserts replaced by farms, pastures, and forests planted by man, as man wills. They cannot bear the thought of the earth becoming man’s garden. In the words of McKibben, “The problem is that nature, the independent force that

has surrounded us since our earliest days, cannot coexist with our numbers and our habits. *We may well be able to create a world that can support our numbers and our habits, but it will be an artificial world. . .*"⁶⁹

The influence of the doctrine of intrinsic value and of its implicit hatred of mankind is present in the usage of the very word *pollution*. More and more, "pollution" is used to mean any change in the state of nature caused by man. It is only from this perspective that one can label as "pollution" such things as the possible changes in the chemical composition of the earth's atmosphere which may result as the by-product of man's productive activity. Consider. Somewhat more carbon dioxide in the atmosphere or less ozone in the stratosphere (assuming these things were in fact the result of human productive activity) does not make the atmosphere dirty. It merely makes it somewhat different, requiring a somewhat different response on the part of human beings in order most efficiently to adapt to their environment. It is of a radically different character from pollution in the legitimate sense of, say, the discharge of human fecal material into drinking water. Its being subsumed under the concept of "pollution" serves as a vehicle to attack productive activity.

Closely related to the misuse of the word *pollution* is the practice of describing the chemical emissions into the atmosphere entailed in industrial production, as using the atmosphere as "a garbage dump." The meaning of the word "garbage," according to *The American College Dictionary*, is "1. refuse animal and vegetable matter from a kitchen. 2. any foul refuse; vile or worthless matter." To use the term to describe chemical emissions is an unwarranted extension of the term having no other purpose than to attack productive activity and man's life. Ironically, garbage is precisely that allegedly good "biodegradable" material the environmentalists are so fond of. A further irony is that precisely when human beings eliminate garbage, by burning it and thus reducing it to mere carbon and gases, they are denounced for dumping garbage—into the atmosphere.

Like the use of the word *concupiscence* in an earlier age to describe sexual desire, the use of the word *pollution* to describe essential aspects of the productive activities of an industrial society represents an attempt to defame an entirely proper human capacity by means of using an evil sounding name for it.

3. The Collectivist Bias of Environmentalism

As I have said, the ecology movement could not have nearly the following and the influence it does if its basic ethical perspective were known. Thus, most of the time it asserts that it actually has the welfare of people in mind, and that it is in the name of human well-being that it

attacks technology and economic progress. When it does this, it proceeds as though despite all the best efforts of scientists, engineers, and businessmen to improve human life and well-being they systematically fail, at least in the long run. Here, as in the case of alleged global warming, the movement apparently claims to be able to see from the vantage point of its allegedly superior wisdom that the true road to human well-being requires that mankind not attempt to travel the road to well-being—that it renounce action based on science and technology. Only then, allegedly, by virtue of its renunciation of such activity, and by virtue of its inaction, will mankind avoid self-destruction.

In proceeding in this way, the ecology movement adopts the tactic of taking for granted all the benefits of economic activity and proceeds as though they existed independently of such activity. It then concentrates all of its attention on a few relatively minor phenomena of a negative kind that it traces to economic activity and that it regards as the sum and substance of such activity, such as the emission of certain chemicals into the atmosphere and the consequent creation of smog or, more recently, alleged global warming. Thus, for example, it treats automobiles and power plants as though they were a threat to human life and well-being rather than the enormous source of improvement that they actually are. It proceeds as though people could continue having efficient transportation and electric power and light while being deprived of the means required for their existence: the oil fields, pipelines, and power plants whose construction it fights tooth and nail.

In this process, the ecology movement refers to "conservation" as though it were some kind of magical method of achieving radical reductions in energy use without sacrifice. It claims, for example, that the loss of millions of barrels of oil per day can easily be offset by such means as simply doubling the number of miles per gallon obtained by the average automobile Americans drive. (In its view, evidently, people have up to now simply been too foolish to realize that they could get along just as well with automobiles that would cut their cost of fuel in half. Or, allegedly, if the buyers of cars have realized it, each and every manufacturer and potential manufacturer of automobiles has been too foolish to realize the enormous competitive advantage he would enjoy by meeting the public's demand for such fuel-efficient cars. Or, if the manufacturers have realized it, they have not provided such cars, because each and every automobile manufacturer and potential automobile manufacturer is allegedly part of a "monopolistic conspiracy" or otherwise just arbitrarily refuses to provide the market with such cars. In this way, the environmental movement contemptuously dismisses as of no significance such differences in

automobiles as size, weight, and power of acceleration, and the public's demonstrated preference for larger, heavier, and more powerful automobiles that obtain fewer miles per gallon, over smaller, lighter, less powerful automobiles that obtain more miles per gallon.)

In its masquerade as fighter for human welfare, the technique of the ecology movement consists of an appeal to collectivism and hysteria, in order to create the impression of an overthrow of the harmony-of-interests doctrine of classical economics and the existence of a conflict of interests between the individual and the rest of society.

The truth is that the necessary tendency of economic activity to improve the environment, which was described at the end of the preceding section, is powerfully reinforced by the existence of freedom and free exchange. Freedom and free exchange create an inherent harmony of the rational self-interests of people. When the actions of individuals are free and do not represent the use of force, their effect is necessarily to benefit everyone involved. This is because each individual acts to benefit himself and must at the same time benefit those whose cooperation is to be secured, or else he will not receive it. In addition, no one standing outside the transaction can be harmed, because any evidence of harm to the person or property of others is grounds to prohibit the action as an act of force and violation of freedom. For example, under freedom, if I decide to construct a building, I do so because I judge that I can serve my own interests by doing so. At the same time, I can find workers and suppliers to help me build it and a buyer or tenants to use it, only by making it to the self-interest of all of these parties to deal with me. In addition, the construction of my building must not endanger other, surrounding buildings or passersby; if it does, I am guilty of an initiation of physical force against the property or persons of others, and thus grounds exist to stop me. As a result, the inherent tendency of my action is to produce improvement for others as well as myself, and thereby to improve general well-being.

The stock in trade of the ecologists, however, is to find cases in which perceptible negative consequences to others appear when the actions of large numbers of individuals are cumulated, and then incredibly to exaggerate the importance of those negatives by techniques of hysteria, in the process obliterating all concern for the rights and responsibilities of individuals. The ecologists conclude by arguing that no individual should be allowed to act without first proving that his action will have no adverse "impact" on the "environment."

Thus, for example, ecologists consider such phenomena as the clearing of large areas of land for the establishment of farms. Such clearing of land may sometimes have the effect of raising the water level downstream and

thereby causing flooding, as allegedly occurred along the Mississippi River as the result of the settlement of the Midwest. Likewise, they consider the fact that the movement of large numbers of people into the same area may result in traffic congestion. And in exactly the same way, they consider the effects of hundreds of millions or billions of people burning fossil fuels, using CFCs, and so on, which actions allegedly result in global warming and ozone depletion.

In their treatment of all such cases, the ecologists show themselves to be collectivists. They are prepared to hold individuals responsible for negative effects that are not the responsibility of individuals qua individuals, that is, for negative effects which are not caused by any individual, but which are the result of the combined actions of the members of the group to which the individual belongs. Such negative effects, not being the responsibility of any individual, should properly be regarded as the equivalent of acts of nature, and individuals should be left free to respond to them in the way most to their advantage. Instead, the ecologists seek to paralyze the individual by harnessing him to the collective—to prohibit him from acting in all cases in which noticeable negative consequences flow from the actions of the collective to which he belongs. And then, of course, instead of allowing the negative effects to be dealt with by the free actions of individuals, the ecologists can see no other solution than that of collective action, in the form of government planning.

In such cases, the ecologists mistakenly assume that they have the right to prohibit the actions they find displeasing. Actually, however, they do not. The fact that the separate, independent actions of vast numbers of people may result in significant negative consequences to someone by virtue of their cumulative effect is simply not the responsibility of any of the individuals concerned. It should not be a basis for prohibiting his actions. To prohibit the action of an individual in such a case is to hold him responsible for something for which *he* is simply not in fact responsible. It is exactly the same in principle as punishing him for something he did not do.

The harm that results from the cumulative actions of the whole category of individuals, without any of the individuals qua individuals being responsible, should, as I say, be regarded as having the same status as harm caused by acts of nature. That is, such phenomena as floods downstream possibly resulting from the actions of tens or hundreds of thousands of separately acting individuals, each of whom as an individual causes no perceptible harm to anyone, should be regarded in exactly the same way as floods that result when few or no human beings are present upstream. Exactly the same is true of the similar phenomena, or alleged phenomena, of global

warming, ozone depletion, and acid rain. As the result, or alleged result, of the actions of vast numbers of individuals, each of whom has no individual responsibility for them, they should be regarded in exactly the same way as one would regard global warming, ozone depletion, or acid rain existing totally apart from modern economic activity. That is, they should be regarded as phenomena of nature, for which no individual human being is responsible and to which individual human beings must be left free to respond.

Those who are adversely affected in such cases should not blame anyone, but should simply be left free to take steps to protect themselves by engaging in the appropriate form of productive activity. In the case of downstream flooding, this might consist of building dikes or flood-control channels; in the case of traffic congestion, it might consist of building more roads, or moving elsewhere.⁷⁰ The kind of responses appropriate to the alleged cases of global warming, ozone depletion, and acid rain have already been explained, in the preceding section. The all-encompassing appropriate answer to the ecologists in all the cases they bring forward of this kind is simply that under capitalism, man will deal with the negative forces of nature resulting as by-products of his own activity in precisely the same successful way that he regularly deals with the primary forces of nature.

Furthermore, it must never be forgotten that the harm done in these cases is necessarily minuscule in comparison with the good achieved. The ecologists use the technique of weighing the full harm against the actions of each individual alone. For example, they argue that an individual farmer should not be allowed to clear his land because if hundreds of thousands do so, flooding may be caused downstream. The fact is, the individual farmer accomplishes a substantial amount of good and no perceptible damage. If one wants to look at the damage caused by all the farmers together, it must be compared with the enormous good accomplished by all the farmers together.

The development of the Midwest, for example, obviously represented a far greater gain to virtually everyone than the occasional greater flooding in the New Orleans area, which may have been its result, represented a loss. (It represented a gain even to the people who lived in the areas subject to occasional greater flooding.) Yet the logic of the environmental movement, had it been present and guided government policy in the nineteenth century, could well have prohibited the development of the Midwest and required the American people to remain bottled up behind the Appalachian Mountains. (One can easily imagine a nineteenth-century campaign of ecological hysteria centering not only on the fear of such allegedly horrifying results as higher flood levels along

the Mississippi, but also on the pollution of many rivers and lakes, and on the disturbance of the habitat of this or that species. The impending near extinction of the buffalo would probably have been considered sufficient by itself to stop the settlement of the Midwest, if the environmental movement had existed at the time.)

Precisely the same principles apply to the cases of global warming, ozone depletion, and acid rain. Each individual who uses an automobile, electricity, and so on, derives immense benefits from doing so and causes absolutely no perceptible harm to anyone. The same is true of the manufacturers of automobiles and is probably true even of the very largest individual electric utilities and chemical companies, in connection with the creation of acid rain. The prohibition or curtailment of such activities for the sake of preventing global warming, ozone depletion, or acid rain is fully comparable to prohibiting or curtailing the development of the Midwest for the sake of preventing floods at New Orleans. It is the attempt to stop production and its immense benefits for the sake of avoiding the relatively minuscule negative effects of the by-products of production. It is comparable to prohibiting the use of machinery and the achievement of all its benefits for the sake of avoiding such a thing as short-run technological unemployment.

Of course, it is possible in productive processes for individual producers to cause *perceptible* negative effects on others. Even if this is not so in the case of acid rain, it was certainly so in the days when power plants and steel mills generated large quantities of soot which fell in the surrounding territory, and which the very tall government-mandated smokestacks that result in acid rain were designed to overcome.

In such cases, an important principle is that of who holds prior established rights. For example, if a steel mill begins operations in the open countryside, where the surrounding land is simply unused, and the landowners make no complaint over a period of several years or more, it appears reasonable to say that the steel mill acquires a right to continue its operations. The same, of course, would certainly be true if the steel mill made a mutually agreeable payment to the owners of the surrounding land as compensation for the negative effects of its operations. In either case, the price at which the surrounding land sells would tend to be cheaper in reflection of the negative consequences caused by the existence of the nearby steel mill. On the basis of such considerations, the owners of the surrounding land would have no justifiable basis for complaint. Justifiable grounds for complaint exist in cases in which an action of a producer creates some new negative effect, which has not become an established right, and which was not

reflected in the price that the present owners of the surrounding land paid for it. In such cases, the only proper way in which the producer can proceed is by buying the right to do so from the owners of the affected surrounding land.⁷¹

In the absence of modern technology, the existence of densely populated areas necessitates considerable, individually perceptible mutual impositions by the inhabitants on the health, cleanliness, and property of one another. In the absence of low-cost iron and steel pipe, for example, there is virtually no alternative to using the open streets as sewers. In the absence of the automobile, there is no alternative to the streets being filled with horse droppings. In the absence of heating oil, natural gas, and electric power, there is no alternative to the soot produced by wood or coal-burning fires which falls on neighboring properties as well as on one's own.

If people are to live in towns and cities in such circumstances, they must put up with such problems. However, thanks to economic progress, it becomes economically and financially feasible to reduce the extent of these impositions. This comes about as the result of the continual widening of technological alternatives, reductions in cost, and fall in prices relative to incomes that economic progress represents.⁷² It is in this spirit that one should fundamentally understand such public health measures as the requirement of sewer hookups as a precondition to housing construction. It is in this spirit that one should understand such measures as the city of London's requiring some years ago the gradual replacement of coal-burning furnaces with natural gas and electric furnaces. Measures of this kind, though they were better carried out by organs other than local governments, namely, by associations of private property owners, are consistent with the principle of individual rights. Furthermore, they are fully in the spirit of economic progress. They thus have nothing in common with the kind of measures characteristically advocated by the environmental movement.

The ecologists employ the technique of confusing the effects of the actions of specific individuals with effects that can be caused only by cumulating the actions of large numbers of individuals to downplay the importance of positive individual contributions. For example, the Sierra Club has argued against government approval of the search for oil in Northern Alaska on the grounds that if oil were found there, it would represent only a 200-day supply, which is too little to justify the project, according to the Sierra Club. In a mailing to its members, the executive director of the Sierra Club declared:

Imagine! The supporters of drilling in the Refuge are

willing to ravage a fragile ecosystem. To build airfields, pipelines and roads where caribou, polar bears and wolves, golden eagles, swans and snow geese make their home. To destroy a wilderness—perhaps North America's greatest wilderness—forever denying the right of future generations to marvel at its majesty. And why. For a 19% chance that they will find a 200-day supply of oil!⁷³

Thus, if an individual oil field succeeds in adding 200 days' worth of oil to the world supply, it is allegedly too small to be worth developing. Presumably, each oil field must be capable of dramatically increasing the entire world's supply—adding at least several years' worth all by itself—if it is to be allowed to be developed. The implication of this position is that no one is to be allowed to act unless his action all by itself can have absolutely stupendous positive consequences, and is virtually certain to achieve them. Since the world supply of anything is almost always produced by large numbers of producers, each of whom produces a relatively small percentage of the total supply, the adoption of this standard easily serves to prohibit increases in production by practically every private individual or firm.

The leadership of the Sierra Club almost certainly knows that a 19 percent chance of finding oil is almost four times the chance that is present in most exploratory efforts and that oil in the area concerned is actually found seeping out of the ground. It is not so illogical as seriously to believe that roads and pipelines would be constructed without definite proof having first been obtained that substantial quantities of oil were actually present in the region. Nor is it so illogical as to believe that future generations will be able to go and marvel at the "majesty" of the area without the benefit of roads and airfields to bring them to it (that is, if the area were not a frozen barren desert and thus actually had majesty worth travelling to see). And the Sierra Club is almost certainly capable of realizing that if, as might be expected, the field contributed to production over a 20-year period and added just a 10-day supply to the otherwise existing supply of oil in each of those years, that would represent an almost 3 percent increase in the world supply of oil in each of those years. It is capable of realizing that such an increase in supply is approximately equal to the reduction in supply caused by Iraq's invasion of Kuwait and the consequent embargo imposed against Iraq, and that it would likely have as much effect in reducing the price of oil as the Iraqi invasion had in increasing it. The Sierra Club's leadership undoubtedly is aware of all of these things.

Nevertheless, it attempts to trivialize the importance of the project by setting an impossible standard of what must be produced in order for the project to be considered worthwhile.⁷⁴ Having trivialized the project in this way, it can then rank the project below the alleged value of

maintaining absolutely undisturbed the wildlife in the region and the existing state of the mere ground itself, to neither of which anyone attaches any actual value.

Thus a major technique of the environmentalists is to *confuse the individual with the collective*—to hold the individual responsible for the negative effects resulting from the actions of the whole category of individuals to which he belongs and to demand that his positive actions be on a scale great enough dramatically to benefit the whole of society.

Confusion of the individual with the collective, indeed, of the individual with the cosmic, is present also in the environmentalists' scare tactics. For example, Carl Sagan writes: "The typical temperature *difference* averaged over the whole world between an ice age and an interglacial is only 3° to 6°C (equivalent to 5°F to 11°F). This should immediately sound an alarm: A temperature change of only a few degrees can be serious business."⁷⁵

Of course, Dr. Sagan and every housewife knows how easy it is to bring a pot of water to a boil, let alone to raise its temperature by a mere few degrees. On this basis, he apparently believes that raising the temperature of the hundreds of millions of cubic miles of the earth's atmosphere and oceans and thus the surface of the whole earth a few degrees is a comparably easy matter, which we are readily capable of doing if we do not employ him and his colleagues to take charge of our lives.

Indeed, as should now be clear, the mentality of collectivism permeates environmentalism. It contributes to the notion of a "fragility of nature" in all of its immensity comparable to the fragility of an individual's possessions or an individual's life. As we have seen, it plays a vital role in the existence of the belief that there is an "environmental crisis," in projecting that only incompetent governmental action is available to deal with the changing environmental conditions allegedly caused by man's productive activities, and not the intelligent actions of individual human beings. That is, it is totally ignorant of the intelligent actions of individuals coordinated by the price system, as the means of solving such problems. Indeed, the very notion of an "environmental crisis" is the result of a preexisting mentality of collectivism. If not for the prevalence of the mentality of collectivism, human productive activity would have gone on just as smoothly and successfully as before, with individuals being happily and legitimately unconcerned with avoiding the effects resulting from the actions of the collectives of which they are members and easily dealing with such effects as and when they arose.

Environmentalism and Irrational Product Liability

Confusions—inspired by collectivism—concerning the responsibility of individuals also arise in other important

areas, which may or may not be connected with environmentalism. Thus, for example, an individual criminal is held not to be responsible for his actions. Instead, responsibility is held to lie with "society" and with other individuals, who somehow convey negative social attitudes to such individuals, such as lack of respect for their race or national origin.

The fallacy of such misplaced responsibility is present in the case of product liability, when large manufacturers who are aware that statistically so many accidents of a certain kind will occur per hundred thousand or million units of their product are held to be morally responsible for those accidents, especially if it is possible to take steps to prevent or mitigate them and they do not do so. To illustrate the logic of this view, one might imagine a fruit company that imports tens or hundreds of millions of bananas. Some percentage of the peels from these bananas will end up in places where people can slip on them and suffer serious injury. Never mind who thoughtlessly threw away the banana peels or who was responsible for watching where he walked. If it is known that statistically one person will break his neck or arm as the result of every X million bananas imported, the logic of this view implies that the fruit company somehow has responsibility for the injuries people suffer as the result of slipping on banana peels. (Presumably, it should be obliged to work on a nonskid banana peel.)

While the example of banana peels may seem far-fetched, because no one has gotten around to bringing suit on this basis, it is difficult to distinguish the logic of it from cases which have been brought and won by the plaintiffs. For example, the Ford Motor Company was held responsible for the fact that in a certain category of collision the fuel tank of its Pinto automobile was apparently capable of exploding. On this view, the responsibility of the individual(s) who caused the accident was dropped from view, and it was assumed that because statistically there could be a certain percentage of such accidents, the manufacturer was responsible: he allegedly should not only have known about such a statistical probability but also have taken steps so that people would not suffer such grave injury in the accidents for which somehow none of them allegedly bore responsibility.

The logic of holding an individual responsible for the actions of others is also present in legislation requiring soft-drink manufacturers to charge return deposits on cans and bottles, which they would normally not seek to have returned and on which, therefore, they would not charge such deposits. The manufacturers are viewed as responsible for the actions of their customers, who simply leave the cans or bottles lying on the ground.

The effect of imposing such wrongly increased liability on producers is to increase costs and prices for every-

one. And because of the grave uncertainties created wherever the sums in question are substantial, to prevent the introduction of new products, and sometimes, as in the case of the manufacture of small private airplanes, cause even the discontinuation of existing products. Irrational product liability is an important ally of the ecology movement in its campaign to end economic progress and reduce the standard of living.

Environmentalism and the Externalities Doctrine

The influence of the environmental movement has been promoted in the science of economics by a pernicious doctrine known as the theory of "external costs and benefits" or, sometimes, simply the theory of "externalities."⁷⁶

The externalities doctrine must be understood against the background of the fact that economists realized early that the pattern of spending adopted by consumers determines the pattern of spending adopted by businessmen, whose products must sooner or later serve to satisfy consumers. They saw, for example, that if consumers spent more money for shirts and less for shoes, businessmen would be impelled to spend more money in producing shirts and less in producing shoes. The economists recognized in this the operation of a profoundly benevolent principle enabling people to obtain what they wanted by virtue of the ways in which they spent their money.

The supporters of the externalities doctrine are not satisfied with the fact that the spending pattern of consumers determines the spending pattern of businessmen. They add the further arbitrary demand that the individual should be able to lay claim to compensation for all the benefits his action causes to the rest of mankind and should be liable for all the costs it imposes on the rest of mankind, even though the benefits and costs in question are not subjects of purchase and sale in the normal context of the individuals concerned. From the perspective of the externalities doctrine, it is a flaw of capitalism whenever an individual's action provides any kind of benefits to others for which he is not compensated, or imposes any kind of costs on others for which he does not compensate them. It calls upon the government to enter the scene and set matters right by deciding who owes what to whom and then effecting the necessary redistribution of wealth and income.

The alleged environmental damage caused by economic progress is regarded as falling under the heading of external costs, and it is urged that those responsible be held liable for damages. For example, it is argued that everyone whose car or factory emits any chemical into the air should be made to pay a share of whatever damages may be caused by the total volume of emissions of that chemical.

It is believed by many economists, including some who are usually staunch defenders of capitalism, that many of the demands of the environmental movement could be satisfied in this way within the framework of a capitalist society. They regard the demands of the externalities doctrine as fully consistent with the principles of capitalism, indeed, as representing a more-perfect implementation of those principles. In their eyes, the demand for compensation for all the benefits one causes is merely the principle of being paid for one's work; the demand for liability for all the costs one imposes on others appears to them as an implication of the principle of accepting responsibility for one's actions.

The externalities doctrine is a further confusion respecting the responsibilities of individuals. Even apart from imposing responsibility on individuals for results that individuals qua individuals do not cause, the error of the externalities doctrine is that it states matters far too broadly. A moment's reflection will show that one should *not* be compensated for *all* the benefits one causes, nor be made liable for *all* the costs one imposes. One should be compensated only for those benefits one gives to others which those others freely contract to receive. One should be liable for damages to others only insofar as one's action causes demonstrable physical harm to the persons or property of specific, individual others.

The broader standard of the externalities doctrine is an invitation to chaos and tyranny, for it opens the door to all kinds of arbitrary claims. According to the logic of the doctrine, beautiful women and the owners of beautiful homes and gardens should demand compensation for the pleasure the appearance of their persons or property brings to others without charge. Even the senders of unsolicited merchandise through the mail should also be able to demand compensation, if their merchandise confers any benefit on the recipients. Indeed, on the basis of the externalities doctrine, it is arguable that people are liable for payment for all the benefits that now come to them freely in the form of the work of all the inventors and authors whose discoveries or creations are not eligible for patent or copyright protection, starting with such contributions as fire and the wheel. Whether or not these payments are to be made to the descendants of the inventors or innovators, to the government, or to some other party, is a separate question. The principle holds that payment must be made for benefits received.

Whatever it may hold about the specific claims of the descendants of inventors and innovators, the doctrine implies that every living inventor or innovator should be prepared to meet demands for compensation by those displaced by the competition he inaugurates. For example, the doctrine implies that Henry Ford should have been made to pay for the support of unemployed black-

smiths and horse breeders, as though the latter had a right to go on in their routine irrespective of Ford's improvements and irrespective of the voluntary choices of the buyers of means of transportation.

It is a distortion of sound principles and totally inappropriate to call for payment for every benefit bestowed or to demand compensation for every cost imposed. It is in the nature of a division-of-labor, capitalist society to bestow enormous benefits for which people do not have to pay. Indeed, in such a society perhaps 99.9 percent or more of everyone's standard of living comes to him as an "external benefit" provided by the thinking of others past and present. It is also in the nature of such a society to impose various costs of a minor and transitional nature in the process of improving the methods of production and raising the general standard of living. The externalities doctrine implicitly represents a two-pronged attack on a division-of-labor, capitalist society: its logic would deprive people of the benefits such a society freely gives them, by making them pay the equivalent of those benefits. And, by making those who are the source of the benefits bear unnecessary and unjust costs in the process of bringing them about, it would operate to prevent the achievement of the benefits in the first place.⁷⁷

There is no better place than this to observe that in addition to being used in support of environmentalism, the externalities doctrine is used as a fundamental justification for government activity beyond defense against the initiation of physical force. It is argued that insofar as important benefits are obtainable without individuals having to pay for them, a free market cannot function successfully. A typical case advanced to illustrate this claim is that of lighthouses, which, once they exist, benefit all the ships passing in the night, whether the ships' owners have helped to pay for the lighthouses or not. It is argued that in this case, the possibility of avoiding payment and getting by as a "free rider" on the strength of the contributions of others will result in large numbers of shipowners refusing to pay for lighthouses and thus in either preventing their construction altogether or making their construction and operation less adequate. More broadly, as a general principle, it is argued that in such circumstances vital services will not be performed, or will be performed inadequately, because too many people will be hoping to take advantage of a "free ride."

The substance of the free-rider argument is the gratuitous assumption that people lack sufficient rationality to act in their own interest in cases in which they cannot receive corresponding direct payment, and hence must be forced to act in their own interest in such cases. The clearest contradiction of this belief is the success of the

activities carried on by countless private charities. In their case, individual donors give without expecting to receive any corresponding material payment, direct or indirect. Although the free-rider doctrine's supporters are focused on such cases as lighthouses, the logic of the doctrine implies that all charitable activities should be performed by the government. The doctrine also implies that in every case in which there are benefits of any description which are not paid for, the government is to be put in a position in which it can demand a blank check, since no one can actually determine what voluntary payments made by the citizens on their own would be "adequate."

The truth is that private citizens are capable on their own of providing for necessary activities for which it may not be possible to arrange the normal system of payment for goods or services received. This is true even in cases requiring the cooperation of millions of individuals. There is no reason why in such cases individuals could not agree to contribute to the financing of a project on a contingency basis, namely, on the basis of a sufficient number of other individuals making the same pledge. Whether it is a matter of a hundred ship owners concerned with constructing a lighthouse or a million property owners concerned with building a dam to prevent flood damage (or perhaps installing catalytic converters on their automobiles to reduce smog), there is no reason why an arrangement could not be made whereby the individual pledges his contribution on the condition of an equal or otherwise comparable contribution being pledged by a certain percentage of other such individuals. For example, the individual ship owner or property owner might agree to pledge a definite sum on the condition that half or two-thirds of the other ship owners or property owners made the same or a comparable pledge. Only when it was established that the necessary number of pledges had been made, would the pledges of the various individuals become binding. In such cases, there might be a class of free riders, but they would certainly not stop the activity from proceeding. (To some people, of course, such a procedure may appear cumbersome. Nevertheless, it is an insignificant price to pay for maintaining consistent respect for the rights of the individual.)

Finally, although the payment for a good or service in such circumstances might be less than it would be if somehow the usual circumstance prevailed of receipt of the benefit being directly contingent on payment being made, it by no means follows that the amount of benefit provided would be any less under private control than under government control. Government is inherently wasteful. As a result, it needs to spend much more money than a private organization to provide the same amount

of goods or services. True, if it spends still more than that, it may provide more of the good or service than would be provided privately. But no objective basis exists for showing that it should provide more. In fact, the one outstanding objective fact in the situation is that in taking responsibility for activities beyond defense against the initiation of force, the government does something it should not do: namely, it initiates physical force against people.⁷⁸

4. The Economic and Philosophic Significance of Environmentalism

The American people must be made aware of what environmentalism actually stands for and of what they stand to lose, and have already lost in economic terms as the result of its growing influence. They must be made aware of the environmental movement's responsibility for the energy crisis and the accompanying high price of oil and oil products, which is the result of its systematic and highly successful campaign against additional energy supplies.⁷⁹ They must be made aware of its consequent responsibility for the enrichment of Arab sheiks at the expense of the impoverishment of hundreds of millions of people around the world, including many millions here in the United States. They must be made aware of its responsibility for the vastly increased wealth, power, and influence of terrorist governments in the Middle East, stemming from the high price of oil it has caused, and for the resulting need to send an American army to the region. In the absence of the environmental movement, the war in the Persian Gulf would not have been necessary. For in that case, the Iraqi dictator would not have been able to achieve a significant military build-up: he would not have had the oil revenues to finance it.

The American people must be made aware of how the environmental movement has steadily made life more difficult for them in prohibiting, or increasing the cost, of one economic activity after another. They must be shown how, as the result of its existence, people have been prevented from taking such necessary and relatively simple actions as building power plants and roads, extending airport runways, and even establishing new garbage dumps. They must be shown how the history of the environmental movement is a history of destruction: of the atomic power industry; of oil fields, oil refineries, and oil pipelines; of coal mines; of metal smelters and steel mills; of the Johns Manville Company and the asbestos industry; of logging companies, sawmills, and paper mills; of cranberry growers and apple growers; of tuna fishermen—to name only those which come readily to mind. They must be shown how the environmental movement has been the cause of the wanton violation of

private property rights and thereby of untold thousands of acres of land not being developed for the benefit of human beings, and thus of countless homes and factories not being built. They must be shown how as the result of all the necessary actions it prohibits or makes more expensive, the environmental movement has been a major cause of the marked deterioration in the conditions in which most people now must live their lives in the United States—that it is the cause of families earning less and having to pay more, and, as a result, being deprived of the ability to own their own home or even to get by at all without having to work a good deal harder than used to be necessary.

Ironically, while claiming to be concerned about the “environmental impact” of everyone's actions, the environmental movement is utterly unconcerned about the *economic* impact of its own actions. It demands that before human beings be allowed to act, they first prove an impossibility: namely, that their actions will bring no harm to any species, indeed, any geologic rock formation, anywhere on earth, for an indeterminately long period of time. It itself, however, is to be free to act without any concern whatever for the consequences of its actions on the lives and well-being of human beings.

The environmental movement does not care to know that the rise in the price of oil and all other increases in the cost of living that it has brought about necessarily have a negative impact on human health as well as on happiness, and have actually cut short an undetermined number of human lives. This is because as a consequence of having to meet higher costs of living, there are always at least some people who are put in the position of having to do without, or at least postpone, such things as medical checkups and necessary repairs on their automobiles, home heaters, or wiring systems, and who, because of this, suffer injury or even death from illnesses or accidents they might otherwise have avoided.

This kind of result is the effect of all legislation which increases costs. Such legislation always has negative economic consequences which are not immediately obvious. For it embraces the consequences of millions of people having to respond to some degree of straightening of their financial circumstances and corresponding decline in their standard of living.⁸⁰

Even more insidious, legislation that increases costs, or in any way reduces economic efficiency, has a *cumulative* negative effect on the standard of living, which results from the fact that it reduces the ability of the economic system to accumulate and maintain capital. This is the result of the vast diversion of capital from normal, productive uses to uses required by law to be in compliance with the ever swelling array of “environmental” regulations—for example, the vast sums of capital

that must be unnecessarily expended to remove asbestos from buildings, to replace underground gasoline storage tanks at service stations, or to prevent the escape of ordinary chemical fumes from dry cleaning establishments. Capital diverted in this way is drawn not only from the production of consumers' goods but also from the production of subsequent capital goods. This last reduces the ability of the economic system to produce more capital goods than it uses up in production and thus its ability to increase the supply of capital goods, on which depends its ability to increase production in the future, including the future supply of capital goods. Carried far enough, by means of enough wasteful and destructive environmentalist regulations, the reduction in the production of capital goods may be so great as to make impossible even the replacement of the capital goods used up in production. If that happens, the subsequent ability to produce declines, including the subsequent ability to produce capital goods.⁸¹

In sum, the American people need to be shown how the actual nature of the environmental movement is that of a *virulent pest*, consistently coming between man and the work he must do to sustain and improve his life.

If and when such understanding develops on the part of the American people, it will be possible to accomplish the appropriate remedy. This would include the repeal of every law and regulation in any way tainted by the doctrine of intrinsic value, such as the endangered species act. It would also include repeal of all legislation requiring the banning of man-made chemicals merely because a statistical correlation with cancer in laboratory animals can be established when the chemicals are fed to the animals in massive, inherently destructive doses. And it would include abolition of the Environmental Protection Agency, which is one of the foremost practitioners of pseudo-science in the United States today and the leading instrument of the economic destruction that is practiced in the name of environmentalism. The overriding purpose and nature of the remedy would be to break the constricting grip of environmentalism and make it possible for man to resume the increase in his productive powers in the United States in the remaining years of this century and in the new century ahead.

As I will show in the remainder of this chapter, the philosophic significance of environmentalism is more profound than its economic significance, which is certainly great enough. The cultural acceptance of a doctrine as irrational as environmentalism makes clear that the real problem of the industrialized world is not "environmental pollution" but *philosophical corruption and moral depravity*.

As an indication of the depths of the depravity into

which contemporary society has fallen, I offer the following excerpt from a recent news story. I believe that the actions described in this news story rival in absurdity, and far exceed in viciousness, those described in the ancient report that the Roman Emperor Caligula had made his horse a member of the Roman senate.

A New York commodities dealer pleaded guilty in Federal District Court today to destroying 86 acres of wetlands on his hunting retreat and was ordered to pay a \$1 million fine and \$1 million as restitution.

The dealer, Paul Tudor Jones 2d, was also banned from hunting migratory wildfowl through 1991—"restitution for the birds," said Judge Frederick Smalkin, who sentenced him.

. . . Under the plea bargain, he was fined \$1 million, ordered to pay \$1 million in restitution to the National Fish and Wildlife Foundation and ordered to restore the 86 acres, said Jane Barrett, assistant United States attorney. Mr. Jones was placed on 18 months' probation and barred from developing 2,500 of his 3,272-acre estate. Wetlands are critical because they filter pollutants and provide wildlife habitats.⁸²

The meaning of this news story is that the rightful owner of a piece of property has been wantonly deprived of his property—the substance of it—and then outrageously humiliated by a gang of smirking tormentors, indistinguishable in the nature of their behavior from hoodlums robbing an innocent man on the street. For what else does it mean to seize the power to determine the use of someone else's property, without his consent and without compensation, and then punish *him* for daring to use what is in fact absolutely his right to use, and no one else's, and, in the process, as a calculated act of outrage, make *him* pay compensation—for his use of his own property—to birds. The only difference between this and the activities of ordinary hoodlums is that the hoodlums in this case wear the robe of a U.S. district judge and occupy the office of an assistant U.S. attorney.

5. Environmentalism, the Intellectuals, and Socialism

Environmentalism is the enemy not only of industrial civilization, individualism, and capitalism, but also of technology, science, human reason, and human life. It must be fought in the name of these values. Those who should be leading the fight against it are the intellectuals. They, presumably, are men of the mind and thus automatically advocates of reason, human life, and all the fundamental human values that are obviously based on reason, such as science and technology.

Unfortunately, of course, it is not working out that way. If the intellectuals were opposed to environmentalism, it would never have achieved the following it has.

It would probably be nonexistent; if it existed, it would be utterly disreputable. The fact is that the great majority of today's intellectuals, who should be fighting for human values, either do not know enough to do so, or have become afraid to do so, or, still worse, have themselves become the enemies of human values and are actively working on the side of environmentalism.

It is important to explain how this has happened.

I believe that to an important extent the hatred of man and distrust of reason displayed by the environmental movement are a psychological projection of many contemporary intellectuals' self-hatred and distrust of their own minds, which have been made much more acute as the result of the visible worldwide collapse of socialism, and the fact that they, as the advocates and apologists of socialism, have been responsible for the destruction it has wrought. As the parties responsible for socialism—for a system which has brought poverty and tyranny to every country upon which it was imposed, from Soviet Russia and the East European nations to mainland China, Indochina, Ethiopia, Angola, and Cuba—they have certainly been “a plague upon the world.” And if socialism had in fact represented reason and science, as most intellectuals cannot help but continue to believe, there would be grounds to distrust reason and science. For then, reason and science would have been responsible for scores of millions of murders.

Of course, it is not reason and science that have been responsible for those murders. What have been responsible are the vicious, irrational ideas and immoral character of the majority of the last several generations of intellectuals. Although it is never spoken of, the undeniable fact is that the hands of several generations of Western intellectuals are covered with blood: intellectually and morally, they have been accessories, either before the fact or after the fact, to the mass murders committed by the socialist regimes.

Socialism, international and national, Marxist and Nazi, with all of its wanton destruction and mass murder, was not an accident visited upon mankind from heaven. It was the product of the leading *ideas*, moral and economic, of generations of Western intellectuals. Karl Marx and Friedrich Engels, and all of the intellectuals who elaborated and disseminated their theories, were responsible for socialism's coming to power in Russia and China and everywhere else that the rule of the Communists extended. And all those intellectuals who thereafter refused to know what was going on in those countries, who denied the facts, excused them, or outright lied about them—they bear responsibility for socialism's having remained in power.

And wider than these groups, and fundamentally just as responsible, have been all the hordes of intellectuals

who consistently evaded the ideas of the major theoretical defenders of capitalism and critics of socialism, by ignoring or otherwise refusing to take those ideas seriously. As the result of this evasion, even the very name of Ludwig von Mises, who was the greatest defender of capitalism and critic of socialism of all time, is still unknown to the great majority of intellectuals.

The great majority of intellectuals never bothered to try to understand the intellectual case for capitalism: namely, the economic theories not only of von Mises but also of the Austrian and British classical economists in general, and the political philosophy of John Locke and the Founding Fathers of the United States, and, more recently, the philosophy of Ayn Rand. For the most part, the intellectuals either ignored the intellectual case for capitalism or found it to be an object of amusement, and ridiculed it. Yet such ideas as the law of comparative advantage and the harmony of the rational self-interests of all individuals and groups, which the advocates of capitalism espoused, would have prevented the rise both of Marxism and of Nazism, and the existence of both world wars—if the intellectuals had taken the trouble to understand them.⁸³

Thus, I believe, it is certainly not without cause that the “mainstream” of today's intellectuals has lost confidence in reason. The “intellectual mainstream” has practiced a long-standing policy of massive and willful evasion, in refusing to know what it could have known. It has carried evasion to the point of creating for itself an entirely illusory, make-believe notion of rationality, which has now come crashing down. The intellectual mainstream has so far removed itself from reality that insofar as it turns to introspective evidence for the reliability of reason, it encounters the fact that on the basis of virtually everything it believes, *socialism should work*. As I stated previously, it believes that on the basis of every principle it knows, socialism is ethically and economically superior to capitalism.⁸⁴ And when, at last, the intellectual mainstream is confronted with inescapable, overwhelming evidence of the failure of socialism, rather than admit it has been profoundly, devastatingly wrong, it decides that it has no other choice than to throw up its hands, and take the failure of socialism as the final, convincing proof of the failure of reason. And then, I believe, in appraising what it perceives as its long-standing *adherence to reason* in supporting socialism in the face of rising rivers of blood, it comes to the conclusion that reason can be a devastatingly destructive force, and that those who have adhered to reason are worthy of hatred.

Today's intellectual mainstream, in other words, has very good reason for doubting its mind and hating itself. And thus it is not surprising to see that just as the failure of Marxian “scientific” socialism has become more and

more apparent, the ranks of the “greens,” who hate science and technology, have more and more swelled.

But while the greens have come to hate science and technology, they continue to love socialism. Their conception of a “postindustrial” world is entirely socialistic.

Indeed, it should be realized that the environmental movement has the potential for bringing about the achievement of socialism on a global basis, despite all of the enormous setbacks socialism has recently suffered around the world. The establishment of worldwide socialism is implied in efforts to limit global carbon-dioxide emissions and other global chemical emissions. The setting of such global limits and their allocation among the various countries of the world imply the existence of a worldwide central planning authority with respect to a wide variety of essential means of production. Such an authority would be necessary to determine which countries were to receive the right to burn how much oil or coal, and to carry on how much of virtually any industrial process that emitted chemicals held to be dangerous global pollutants. A global central planning authority is implicit in all potential international efforts to combat alleged global problems. For what is necessarily present in all such efforts is the attempt to organize mankind into a collective unit that acts as one and does so with consistency and coordination, i.e., is centrally planned.

Not surprisingly, one of the most prominent theorists of the environmental movement, Barry Commoner, offers a specific bridge between the doctrines of the socialists and those of the ecologists. The bridge is in the form of an attempted ecological validation of one of the earliest discredited notions of Karl Marx—namely, Marx’s prediction of the progressive impoverishment of the wage earners under capitalism. Commoner attempts to salvage this notion by arguing that what has prevented Marx’s prediction from coming true, until now, is only that business firms have been subsidized by society at the expense of the environment. In effect, says Commoner, the exploitation of the workers has been mitigated by capitalism’s ability—temporarily—to exploit the environment. But now this process must come to an end, and the allegedly inherent conflict between the capitalists and the workers will emerge in full force. In Commoner’s own words:

Marx believed that as capital accumulated, the amount of its fixed forms (productive machinery)—which is related to what he called the “organic composition of capital”—would increase. This is the denominator in the profit equation, and Marx believed that as this denominator grew, the rate of profit would fall. To counteract this trend, the capitalists would need to make increasing inroads on the share of production that goes to the workers. The working class would become increasingly impoverished, and the growing conflict between capitalist and worker would lay

the grounds for the revolutionary change that is the political outcome of the Marxist analysis. . . .

In a curious way, an explanation of why Marx’s prediction has failed to materialize—that is, until now—emerges from the improved understanding of economic processes that is one product of the recent concern with the environment. . . . Since no one has to pay for it, there is nothing to keep pollution from happening. And, as we now well know, the cost is borne by society as a whole. As I pointed out in *The Closing Circle*, “A business enterprise that pollutes the environment is therefore being subsidized by society; to this extent, the enterprise though free is not wholly private.” I pointed out as well that this arrangement leads to “. . . [a] temporary cushioning effect of the ‘debt to nature’ represented by environmental degradation on the conflict between entrepreneur and wage earner, which as it now reaches its limits may reveal this conflict in its full force. . . . In this sense the emergence of a full-blown crisis in the ecosystem can be regarded, as well, as the signal of an emerging crisis in the economic system.”⁸⁵

Thus, according to Commoner, Marx will be proved right after all—on the basis of such things as the accumulation of carbon dioxide in the atmosphere and of beer cans on the beach. These will allegedly compel the world to adopt a social system in which much less is produced in total and in which the members of one group can gain only at the expense of the loss of the members of other groups. In that world, apparently, Commoner will feel at home. It will be a world in which men do not join together to subdue nature for their mutual and increasing benefit, but an impoverished, static world in which men must fight one another for scraps of bread, for the alleged sake of appeasing nature.

Along these lines, it should be realized that the belief in the need for global limits on carbon dioxide and other chemical emissions and thus in the need for international allocation of permissible emissions implies that every country is an international aggressor to the degree that it is economically successful (and thus, of course, that the United States is the world’s leading aggressor). For the consequence of its success is held to be either to push the volume of allegedly dangerous emissions beyond the safe global limit or to impinge upon the ability of other countries to produce, whose populations have more urgent needs. Thus, in casting the production of wealth in the light of a danger to mankind, by virtue of its alleged effects on the environment, and thereby implying the need for global limits on production, the ecology movement attempts to validate the thoroughly vicious proposition, lying at the very core of socialism, that one man’s gain is another’s loss.⁸⁶

Another important illustration of the profoundly socialistic sympathies of the greens is provided by a recent publication of the Sierra Club. This is a collection of essays entitled *Call to Action, Handbook for Ecology*,

Peace and Justice. The book is dedicated to “the people of El Salvador” and has a preface by Jesse Jackson. It contains articles with such titles as “Share the Wealth” and “Co-ops: An Alternative to Business as Usual.” Very significantly, and capturing the essence of the book, the editor declares in the foreword that “[T]he political and economic system that destroys the Earth is the same system that exploits workers. . . .”⁸⁷

The environmental movement, of course, also advocates socialism on a much less grandiose scale than that of a worldwide central planning authority. For example, it also advocates socialism in the form of “bio-regionalism,” which represents socialism on the scale of self-sufficient local regions allegedly distinguished by their biological characteristics.⁸⁸ Indeed, it is to be expected that the environmental movement will increasingly revert to the advocacy of such utterly naïve forms of socialism, which Marx labeled utopian.

Such forms of socialism are more consistent than is Marxism with the movement’s thoroughgoing irrationalism and also with the irrationalist origins of socialism itself. Socialism was originally founded on hatred for reason, science, technology, and the industrial civilization that rests on them. It began as an irrational reaction against the emergence of modern capitalism—as part of a wider “romantic” reaction against the Enlightenment as a whole. But in the nineteenth century, the prestige of capitalism’s underlying values was beyond challenge. The major contribution of Marx to socialism was to separate himself and his supporters from the then existing main body of the socialist movement, which he labeled utopian, and to wrap the socialist program in the mantle of reason and science. Henceforth, socialism was to be in the vanguard of science, enlightenment, and progress. The unraveling of that effort, which is now taking place across the world and which is manifest in the collapse of Communist regimes, means that socialism should be expected to revert to its irrationalist origins, which is precisely what it is doing in the rise of the environmental movement.

Thus, the green movement is the old red movement, deprived of its pretensions to rationality and seeking to evade its guilt by turning on reason itself, as though reason were responsible for the failure of socialism and for all the horrors that have been committed as the result of socialism. The green movement, in other words, is the red movement stripped of the veneer of reason and science and bent on the destruction of reason and science rather than take the trouble to learn what reason and science actually are. The green movement is the red movement no longer in its boisterous, arrogant youth, but in its demented old age.⁸⁹

The only difference I can see between the green move-

ment of the environmentalists and the old red movement of the Communists and socialists is the superficial one of the specific reasons for which they want to violate individual liberty and the pursuit of happiness. The Reds claimed that the individual could not be left free because the result would be such things as “exploitation,” “monopoly,” and depressions. The Greens claim that the individual cannot be left free because the result will be such things as destruction of the ozone layer, acid rain, and global warming. Both claim that centralized government control over economic activity is essential. The Reds wanted it for the alleged sake of achieving human prosperity. The Greens want it for the alleged sake of avoiding environmental damage and for the actual, admitted purpose of inflicting human misery and death (which was also the actual, but unadmitted purpose for which the Reds wanted it). Both the Reds and the Greens want someone to suffer and die; the one, the capitalists and the rich, for the alleged sake of the wage earners and the poor; the other, a major portion of all mankind, for the alleged sake of the lower animals and inanimate nature.

Thus, it should not be surprising to see hordes of former Reds, or of those who otherwise would have become Reds, turning from Marxism and becoming the Greens of the ecology movement. It is the same fundamental philosophy in a different guise, ready as ever to wage war on the freedom and well-being of the individual. In seeking to destroy capitalism and industrial civilization, both movements provide ample potential opportunity for those depraved individuals who would rather kill than live, who would rather inflict pain and death than experience pleasure, whose pleasure comes from the infliction of pain and death.

Unfortunately, there is no lack of such individuals. There are serial murderers in the world. History tells us of mobs that cheered at the sight of human beings being torn to pieces by wild beasts in the arena, and of other mobs that cheered at the sight of “witches” and heretics burning alive at the stake. In our own time, there have been Hitler, Stalin, and Mao, and an array of lesser such gangsters, each with a whole army of sadistic murderers at his beck and call. In every case but that of the serial murderers, there has been some kind of philosophical justification for the murders, such as the security of the State, the will of God, the achievement of Lebensraum, or the establishment of communism and a future classless society. Each of these alleged values supposedly justified the murder of living human beings. As the Communists were so fond of saying, “The end justifies the means.” And now there are the leaders of the ecology movement, whose alleged end is the preservation of such things as wildlife, jungles, and rock formations for their own sake,

and for whose alleged sake they look forward to throttling and destroying industrial civilization and decimating mankind.

Whatever may have been the delusions of religious fanatics and the advocates of racial or class warfare concerning the actual nature of their values, such delusions must wear exceedingly thin in the case of the environmental movement. It is transparently obvious that no one in the world can actually value such things as rock formations, jungles, and dangerous wildlife for their own sake. At best, that would be comparable to valuing pebbles on Mars or gas clouds on Jupiter for their own sake. But what some people can value, unfortunately, is the sight of other human beings suffering. *This* was the value which the Communists and the Nazis sought, which religious fanatics have sought, which serial murderers seek, and which the leaders of the environmental movement seek.

The kind of potential murderers that are to be found in the ranks of the environmental movement are, for the most part, probably not personally violent in any apparent way. In eras that are philosophically and culturally better than our own, they might even pass their entire lives quietly, in modest obscurity, causing harm to no one. In such a better era, Hitler might have passed his days as an obscure paperhanger, Himmler as a chicken farmer, and Eichmann as a factory worker or office clerk. Lenin would probably have been just a disgruntled intellectual, and Stalin perhaps an obscure cleric. But in the conditions of a collapse of rationality, frustrations and feelings of hatred and hostility rapidly multiply, while cool judgment, rational standards, and civilized behavior vanish. Monstrous ideologies appear and monsters in human form emerge alongside them, ready to put them into practice. The ecology movement is just such a movement, with just such a potential. Its expressions of approval for such images as that of a terrified human being, being eaten alive by alligators, is an invitation to torturers and murderers looking for a rationale to call for the exercise of their blood lust.

In my view, the open irrationalism of environmentalism and ecology marks them as nothing but the intellectual death rattle of socialism in the West, the final convulsion of a movement that only a few decades ago eagerly looked forward to the results of paralyzing the actions of individuals by means of "social engineering" and now seeks to paralyze the actions of individuals by means of prohibiting engineering of any kind. If such comparisons are possible, I think the Greens are actually a cut below the Reds and will fade much more quickly from the scene, because of their open irrationality. In the case of socialism and the Reds, there was for many years at least room for some doubt on the part of many people. It was

possible for many years for people to believe that the purpose of the human sacrifices being called for on the part of the rich and the capitalists was to raise the level of the average human being by bringing justice and prosperity to the wage earners, who had allegedly been victimized by the injustices and economic evils of capitalism.

But with environmentalism and the Greens, the first thing to be sacrificed, with scarcely a moment's concern, is the standard of living of the wage earners and the average human being. Indeed, from the perspective of environmentalism, their very existence for the most part represents "surplus population," which prevents the existence of allegedly more important members of animal species. Thus the livelihood of wage earners is to be sacrificed en masse, without a thought, whenever the preservation of any "endangered species" is in question. Everything wage earners buy is to be made more expensive by restricting the production of energy and by imposing one unnecessary cost after another in efforts to escape imaginary terrors.⁹⁰ Environmentalism and the Greens stand for human sacrifice without even the pretense of human beneficiaries. They stand for sacrifice—for destruction—pure and simple. They reveal far more clearly than did socialism and the Reds the actual nature of the doctrine of altruism—of human sacrifice.⁹¹

However justified today's intellectual mainstream is in doubting its mind and hating itself, it has absolutely no basis for blaming its self-doubt and self-hatred on reason. What it took as reason in advocating socialism was never reason, but contemptible ignorance; what it apparently takes as having been loyalty to reason in its adherence to socialism was never loyalty to reason, but willful, defiant ignorance. The roots of the intellectuals' abandonment of reason are to be found not in the collapse of socialism, but in their previous support of socialism.

In the days of a generation or more ago, when the intellectual mainstream still projected confidence in reason, what it took reason to mean in the realm of politics and economics was that a comparative handful of men—an intellectual elite—would arrogate to themselves a monopoly of thought: they would deny the rationality and the independence of the great mass of mankind, and treat everyone as clay for them to mold. Everyone would be compelled to live his life in compliance with their central plan. This was the meaning of socialism and its "social engineering."

Naturally, this project failed miserably. Its failure was certainly not the failure of reason, however. On the contrary, it was the failure of a monumentally *irrational* idea: namely, that the independent exercise of reason by the great mass of mankind could be prohibited in the economic realm, and that somehow, on the strength of a

tiny, insignificant fraction of mankind's collective intelligence, economic success could be achieved for all. Whatever sort of "fatal conceit" this may have been, to use the expression of Professor Hayek, it was not any conceit of reason.⁹² At its base, the entire project was marked by the most profound contempt for reason—for the reason of all of mankind but that of the intellectual elite, which was to rule mankind under socialism.

Today, the intellectuals apparently think they have learned their lesson. They are through with engineering—all of engineering—and through with reason, because they think they know how badly the seemingly best-laid rational plans can run amuck. They now believe that man's acting on nature on a foundation of reason and science is as dangerous as their acting on man on a foundation of "reason" and "science"—on what, in a state of virtual dementia, they choose to believe is reason and science, namely, Marxism and other variants of collectivism. Thus, for example, they believe that the engineering of atomic power plants and dams is as dangerous as the engineering of people that they so long supported in countries such as the former Soviet Union. This is how they act. This is how their behavior can be understood.

The lesson the intellectuals should have learned from the failure of socialism, and still could learn if they finally chose to end their ignorance and read the authors I have mentioned, above all, Ludwig von Mises and Ayn Rand, is the precise opposite of the one they claim to have learned. The correct lesson is that *it is human reason that one must respect*, namely, the reason of the *individual* human being. The substantive meaning of this proposition is that one must respect *individual rights*, as understood by John Locke and the Founding Fathers of the United States, and that the social system which one must uphold, as representing the consistent implementation of respect for individual rights, is *laissez-faire capitalism*. If the intellectuals understood this lesson, then they would understand that what it is dangerous to violate is *laissez faire* in the realm of *human beings*.

The obvious fact is, of course, that man can successfully control nature for the benefit of his life. But the essential politico-economic requirement of his doing so is that the government must not attempt to control man. The individual man or woman is the possessor of reason and the being of ultimate value, each to himself or herself, whose rights must be fully respected. It is these individually sovereign beings who must be free to act upon nature. When they are free, they form and intensify the associations that constitute a division-of-labor society. They create capitalism. They are then capable of acting upon nature with all of the progressively growing success demonstrated in the Western world over the last

two centuries or more.

However, because today's intellectual mainstream does not fundamentally distinguish man from inanimate nature—on such explicit philosophical grounds as determinism—the inference today's intellectuals have apparently drawn from the failure of socialism is the lunatic notion that it is dangerous to violate *laissez faire* in the realm of *nature*. Instead of arriving at the insights of the British classical economists into the natural economic harmonies prevailing among free, rational beings and requiring the absence of government intervention, they believe they have gained insights into alleged natural harmonies prevailing among wild animals and inanimate objects. They call these alleged harmonies "ecosystems," and they believe that the existence of "ecosystems" requires the absence of intervention by rational human beings in nature. In a manner reminiscent of economists arguing against government intervention into the affairs of human beings, they argue against *human* interference with nature and its alleged ecosystems.

Ironically, in arguing in this way, the ecology movement not only seeks the perpetuation of all the horrors of socialism, but also turns out to embody the substance of what was once an unjust caricature of the defenders of capitalism. For it adopts as its actual policy what its intellectual predecessors ridiculed the defenders of capitalism for supposedly believing, namely, that man should not intervene in nature for fear of unleashing unknown forces. That was what the advocates of socialism and government intervention repeatedly accused the defenders of capitalism of believing when the latter stood on the grounds of economic law and its harmonies as an argument against government interference in the economic system. In taking this position, the advocates of capitalism, of course, never advocated a policy of "do nothing," as their socialist and interventionist critics claimed. On the contrary, they have always advocated that *the government* do nothing, so that the *individual citizens* could be free to do what was necessary to achieve their prosperity.

The defenders of capitalism argue both against government interference into the affairs of men and in favor of human interference in nature. The two are merely different sides of the same coin: namely, individuals must be free of government intervention precisely in order for *them* to be able effectively to intervene in nature. It is the individual citizens, not the government, who are the controllers of nature. Whether the government prohibits its citizens from acting on nature on the grounds that it must have a monopoly of such activity, or on the grounds that such activity is simply dangerous, the substance and the consequences are identical: namely, paralysis, poverty, and death. The socialists at least kept up the pretense

that they wanted to achieve human values more efficiently than free individuals could. The environmentalists make clear that their actual purpose in alleging the harmonies of “ecosystems” and arguing against human intervention in nature is the destruction of human values.

In the ecology movement, the Left has reduced itself to a mass of terrified ignoramuses, fearful of all “new-fangled” technology. It reveals itself as a virtual Ma and Pa Kettle of the intellect; a remnant from the Dark Ages, having managed to survive all this time on some kind of intellectual wildlife preserve, to borrow an expression of Ayn Rand’s. What irony it is, that even as this is what the Left has become, its members continue to have the audacity to criticize the advocacy of capitalism and economic freedom as “reactionary.” The more consistent elements of the ecology movement openly urge a return to the Pleistocene—to the Stone Age—in order to live in an alleged harmony with nature. Yet, at the very same time, in the political arena, advocates of some measure of freedom and capitalism, who espouse recognizable elements of the social philosophy formed in the eighteenth century, in the Age of Reason, and found in the United States Constitution, are ridiculed as “dinosaur Republicans”—because they presumably wish to return to the Age of Reason.

It is high time this travesty ended. Its foundation was the Marxist doctrine that socialism was the politico-economic system called for by human reason and thus that movement toward it represented an improvement in human conditions, and, moreover, that mankind was impelled toward progress by automatic historical forces. All of these notions, of course, are totally false and are now discredited in the eyes of the world. Socialism is a vicious, destructive system. Movement toward socialism is movement toward tyranny, poverty, and death. On the other hand, *capitalism* is the politico-economic system actually called for by human reason. Its rising production and improving standards of living represent economic progress. Movement toward capitalism, or toward a more consistent form of capitalism, is what represents progress in the political realm. And, of course, neither movement toward capitalism nor toward socialism, that is to say, neither progress nor decline, is inevitable. Each depends on the influence of ideas: progress, on the influence of rational ideas; decline, on the influence of irrational ideas.

In the environmental movement, the Left now clearly reveals itself to be the most reactionary movement in the history of the world, a movement whose “moderates” seek a return to the economic conditions of a century ago, and whose logically consistent elements openly seek a return to the economic conditions of the Middle Ages or, indeed, of the Stone Age. If ever there were a group of

people who, in the words of a well-known “liberal” of the last generation, needed to be “dragged, kicking and screaming, into the twentieth century”—into the modern world—it is today’s Left: the Greens of the ecology movement.

The transformation of the socialist movement into the ecology movement creates the opportunity for the defenders of capitalism to reclaim their rightful place as the true representatives of science, progress, and enlightenment, and to make sure that wherever intelligent people who value reason are found, they will increasingly enroll under the banners of capitalism.

Furthermore, the advocates of capitalism should now proudly proclaim that they turn to the thinkers of earlier centuries of the modern era for inspiration—to thinkers such as Adam Smith and John Locke—rather than to most of today’s intellectuals. Thanks to the Left’s transformation into the ecology movement, they can now claim, with obvious justification, the same kind of modernity in doing so that men of the Renaissance could claim in looking to the thinkers of antiquity for inspiration rather than to their ignorant contemporaries.

It can readily be conceded that Adam Smith and John Locke and the Founding Fathers of the United States rode in horse-drawn carriages and wore powdered wigs, and that contemporary intellectuals fly in jet planes and wear the fashions of today. But those men were the source of essential ideas on which the Industrial Revolution and our present level of technological and economic development rest. When they rode in horse-drawn carriages, they were thinking the thoughts that made possible the jet planes of today. Today’s intellectuals, although they fly in jet planes, are thinking thoughts which are incompatible with the continuation of industrial civilization. This is now blatantly obvious in their support of the ecology movement and in their growing denunciations of economic progress and transparent efforts to stifle it and undo it. They should certainly not be given any form of credit for the technological and economic achievements of the age in which they live, and which they are in fact out to destroy, and then, on the basis such error, be regarded as superior in any way to the thinkers of earlier centuries who made possible the accomplishments of our own. The nature of their souls and the intellectual level of their philosophy are well expressed in the call “Back to the Pleistocene!” a call which if they do not make themselves, they are certainly not at pains to dispute or capable of disputing. In other words, contemporary intellectuals, with few exceptions, are not at all “modern” or advanced, but backward and primitive, far, far behind intellectuals of earlier generations whom they delight in ridiculing.

The future course of civilization hinges on the extent

to which the advocates of capitalism and reason can take the intellectual offensive against an opposition that is now nothing more than a rapidly decomposing intellectual corpse. Their ultimate victory appears to be assured, provided only that they keep their philosophy alive.

6. Environmentalism and Irrationalism

While the collapse of socialism is an important precipitating factor in the rise of environmentalism, there are other, more fundamental causes as well. Philosophical-cultural forces are at work in the rise of environmentalism which are of the same fundamentality and significance as built modern civilization.⁹³ Only now, centering on a negative appraisal of the reliability of reason, they are working in reverse, to bring about the destruction of modern civilization.

Environmentalism is the product of a growing loss of confidence in reason long predating the collapse of socialism. It is the leading manifestation of a rising tide of irrationalism that is engulfing our culture. As previously mentioned, over the last two centuries the reliability of reason as a means of knowledge has been under a constant attack led by philosophers from Immanuel Kant to Bertrand Russell.⁹⁴ The growth of irrationalism has been manifested in a series of developments each of which has contributed to the rise of environmentalism. Among them have been the loss of the concept of economic progress, the growth of irrational skepticism, a growing decline and outright perversion of education, and the cultural devaluation of man.

The Loss of the Concept of Economic Progress

An important intellectual confusion in the decades prior to the appearance of the ecology movement, which helped to pave the way for it and continues to sustain it, was the loss of very concept of economic *progress*. Somewhere along the line, the seemingly synonymous, but in fact very different, concept of economic *growth* took its place. Only after this change had occurred could the ecology doctrine succeed.

Growth is a concept that applies to individual living organisms. An organism grows until it reaches maturity, then it declines, and sooner or later dies. The concept of growth is also morally neutral, equally capable of describing a negative as a positive: tumors and cancers can grow. Thus the concept of growth both necessarily implies limits and can easily be applied negatively.

In contrast, the concept of progress applies across *succeeding generations of human beings*.⁹⁵ The individual human beings reach maturity and die. But because they possess the faculty of reason, they can both discover new and additional knowledge and transmit it to the

rising generation, which then starts out in life in possession of a larger body of knowledge than did the present generation. If the new generation continues to think, it succeeds in further enlarging the sum of human knowledge and thus it too passes on a larger body of knowledge to its successors than it inherited. And so it can continue from generation to generation, with each succeeding generation receiving a greater inheritance of knowledge than the one before it and making its own fresh contribution to knowledge. This continuously expanding body of knowledge, insofar as it takes the form of continuously increasing scientific and technological knowledge and correspondingly improved capital equipment, is the foundation of continuous economic progress.

Progress is a concept unique to man: it is founded on his possession of reason and thus his ability to accumulate and transmit a growing body of knowledge across the generations. Totally unlike growth, whose essential confines are the limits of a single organism, progress has no practical limit. Only if man could achieve omniscience would progress have to end. But the actual effect of the acquisition of knowledge is always to lay the foundation for the acquisition of still more knowledge. Through applying his reason, man enlarges all of his capacities, and the more he enlarges them, the more he enlarges his capacity to enlarge them.⁹⁶

The concept of progress differs radically from the concept of growth in that it also has built into it a positive evaluation: progress is movement in the direction of a *higher, better, and more desirable state of affairs*. This improving state of affairs is founded on the growing body of knowledge that the possession and application of human reason makes possible. Its foundation is the rising potential for human achievement that is based on growing knowledge.

While it is possible to utter denunciations of too rapid “growth” as being harmful, it would be a contradiction in terms even to utter the thought of too rapid *progress*, let alone denounce it. The meaning would be that things can get *better* too quickly—that things getting better meant they were getting worse.

Irrational Skepticism

A major foundation of the ecologists’ irrationalism that is of long standing is the conviction that whatever we may think we know today about anything, can turn out to be wrong tomorrow, because of the discovery of something new which totally invalidates all of our presumed knowledge about it. This doctrine, which is now increasingly popular, has been a virtual stock in trade of philosophy courses and of higher education in general for several generations. It is on this premise that the ecologists believe and project that every technological

advance is a potential thalidomide.⁹⁷ All of their wild conjectures about mass destruction are reinforced by this premise, of which they are already convinced, in advance of, and apart from, the facts of any particular case.

Such skepticism rests on ignorance of the science of epistemology and on the fallacy of equivocation. It does not understand how man achieves knowledge—how he validates his conclusions and can therefore be rationally confident of them. It assumes, in effect, that all claims to knowledge are equal—the proved and the unproved—and that because some claims to knowledge turn out to be false, any claim to knowledge can turn out to be false. For example, it believes that the very fact that people ardently believed in Ptolemaic astronomy at one time, and were later proved wrong by Copernicus and Galileo, itself raises the possibility that Copernican and Galilean astronomy will someday be proved wrong.⁹⁸

The truth is that knowledge is knowledge and continues to be knowledge for all time to come. It is not overthrown by later discoveries, but is supplemented and expanded by them. The physics of Archimedes was not overthrown, but expanded by the physics of Newton. The geometry of Euclid is as true today as ever, though we now know much more about mathematics than Euclid did. The truths in the writings of Adam Smith are as true today as when he first wrote them, though our knowledge of economics has been greatly expanded by Ricardo, the Mills, Böhm-Bawerk, von Mises, and others. All of technological and economic progress is a confirmation of the fact that the discoveries of later generations *add* to the discoveries of previous ones rather than refute them. If new discoveries constantly refuted previous discoveries, as the skeptics claim, progress of any kind would simply be impossible. Progress rests on the fact that knowledge is a growing sum, in which the contributions of succeeding generations are added to those of previous generations.

Similar reasoning applies to the possibility of accidents, which the ecologists fear so greatly. Despite man's best efforts, accidents sometimes occur. A dam may burst, a building may collapse, a drug may turn out to be unsafe. But by the nature of the case, accidents are the exception—a departure from the normal. Moreover, they are steadily tending to be reduced in frequency and severity as man's knowledge and prosperity grow. Indeed, each accident, if its causes are studied and analyzed, itself tends to prevent a repetition of that accident. Thus, the actual record of man (when he chooses to use his reason) is a steady increase in safety. Few things could be more obvious than that the food, drugs, dams, buildings, bridges, ships, trains, and factories of the twentieth century are incomparably safer than those of the nineteenth century. Apart from the influence of grow-

ing irrationality, progress in safety has continued decade by decade in the twentieth century. (The irrationality I refer to is not only the phenomenon of narcotics use, but also destructive government interference through such means as inflation, confiscatory taxation, and stifling regulation. Such policies can prevent the necessary replacement or maintenance of facilities, let alone their improvement.)

The Destructive Role of Contemporary Education

It is sometimes observed that most of today's high school and college graduates have very little education in science and mathematics and thus do not understand and cannot properly appreciate modern technology. There is considerable merit in these observations, but the problem goes much deeper. Namely, from the earliest grades, *the prevailing methodology of contemporary education systematically encourages the irrational skepticism I have just described.*

To explain how this is the case, I must briefly digress into the history of philosophy.

At the end of the eighteenth century, Immanuel Kant foisted on the intellectual world a distorted version of what reason is, namely, a faculty divorced from knowledge of the real world and limited to awareness of a world of mere appearances created by the human mind itself.⁹⁹ Both in reaction against the Kantian version of reason and on the direct foundation of it, as early as the first quarter of the nineteenth century, reason was being popularly denounced by intellectuals of the "Romantic" era as "a false secondary power by which we multiply distinctions."¹⁰⁰

The Romantics' reaction against the Kantian version of reason can be understood in part in exactly the same way as Ayn Rand has described the later reaction of the Existentialists against it, namely, if "*this* is reason, to hell with it!"¹⁰¹ Romanticism, however, also follows on the direct foundation of Kantianism, which holds that man's mind is incapable of actually knowing reality and thus that "to attain a knowledge of the real, we must go out of consciousness."¹⁰² According to W. T. Jones, a leading historian of philosophy:

To the Romantic mind, the distinctions that reason makes are artificial, imposed, and man-made; they divide, and in dividing destroy, the living whole of reality—"We murder to dissect." How, then, *are* we to get in touch with the real? By divesting ourselves, insofar as we can, of the whole apparatus of learning and scholarship and by becoming like children or simple, uneducated men; by attending to nature rather than to the works of man; by becoming passive and letting nature work upon us; by contemplation and communion, rather than by ratiocination and scientific method.¹⁰³

The Romantics held that "we are nearer to the truth about the universe when we dream than when we are

awake” and “nearer to it as children than as adults.”¹⁰⁴ The clear implication of the philosophy of Romanticism is that the valuable portion of our mental life has no essential connection with our ability to reason and with the deliberate, controlled use of our conscious mind: we allegedly possess it in our sleep and as children.

In its essentials, the philosophy of Romanticism is *the guiding principle of contemporary education*. Exactly like Romanticism, contemporary education holds that the valuable portion of our mental life has no essential connection with our ability to reason and with the deliberate, controlled use of our conscious mind—that we possess this portion of our mental life if not in our sleep, then nevertheless as small children. This doctrine is clearly present in the avowed conviction of contemporary education that *creativity* is a phenomenon that is separate from and independent of such conscious mental processes as *memorization* and the use of logic. Indeed, it is an almost universally accepted proposition of contemporary pseudoscience that one-half of the human brain is responsible for such conscious processes as the use of logic, while the other half is responsible for “creativity,” as though, when examined, the halves of the brain revealed this information all by themselves, perhaps in the form of bearing little labels respectively marked “Logic Unit, Made in Hong Kong” and “Creativity Unit, Made in Woodstock, New York.” Obviously, the view of the brain as functioning in this way is a *conclusion*, which is based on the philosophy and thus interpretative framework of the doctrine’s supporters.

Now, properly, education is a process by means of which students *internalize* knowledge: they mentally absorb it through observation and proof, and repeated application. Memorization, deduction, and problem solving must constantly be involved. The purpose is to develop the student’s mind—to provide him with an instantaneously available storehouse of knowledge and thus an increasingly powerful mental apparatus that he will be able to use and further expand throughout his life. Such education, of course, requires hard work from the student. Seen from a physiological perspective, it may be that what the process of education requires of the student through his exercises is an actual *imprinting* of his brain.

Yet, under the influence of the philosophy of Romanticism, contemporary education is fundamentally opposed to these essentials of education. It draws a distinction between “problem solving,” which it views as “creative” and claims to favor, and “memorization,” which it appears to regard as an imposition on the students, whose valuable, executive-level time, it claims, can be better spent in “problem solving.” Contemporary education thus proceeds on the assumption that the ability to solve problems is innate, or at least fully developed before the

child begins school. It perceives its job as allowing the student to exercise his native problem-solving abilities, while imposing on him as little as possible of the allegedly unnecessary and distracting task of memorization.

In the elementary grades, this approach is expressed in such attitudes as that it is not really necessary for students to go to the trouble of memorizing the multiplication tables if the availability of pocket calculators can be taken for granted which they know how to use; or go to the trouble of memorizing facts of history and geography, if the ready availability of books and atlases containing the facts can be taken for granted, which facts the students know how to look up when the need arises. In college and graduate courses, this approach is expressed in the phenomenon of the “open-book examination,” in which satisfactory performance is supposedly demonstrated by the ability to use a book as a source of information, proving once again that the student knows how to find the information when he needs it.

With little exaggeration, the whole of contemporary education can be described as a process of encumbering the student’s *mind* with as little knowledge as possible. The place for knowledge, it seems to believe, is in external sources—books and libraries—which the student knows how to use when necessary. Its job, its proponents believe, is not to teach the students knowledge but “how to acquire knowledge”—not to teach them facts and principles, which, it holds, quickly become “obsolete,” but to teach them “how to learn.” Its job, its proponents openly declare, is not to teach geography, history, mathematics, science, or any other subject, including reading and writing, but to teach “Johnny”—to teach Johnny how he can allegedly go about learning the facts and principles it declares are not important enough to teach and which it thus gives no incentive to learn and provides the student with no means of learning.

The results of this type of education are visible in the hordes of students who, despite years of schooling, have learned virtually nothing, and who are least of all capable of thinking critically and solving problems. When such students read a newspaper, for example, they cannot read it in the light of a knowledge of history or economics—they do not know history or economics; history and economics are out there in the history and economics books, which, they were taught, they can “look up, if they need to.” They cannot even read it in the light of elementary arithmetic, for they have little or no internally automated habits of doing arithmetic. Having little or no knowledge of the elementary facts of history and geography, they have no way even of relating one event to another in terms of time and place.

Such students, and, of course, the adults such students become, are chronically in the position in which to be

able to use the knowledge they need to use, they would first have to go out and acquire it. Not only would they have to look up relevant facts, which they already should know, and now may have no way even of knowing they need to know, but they would first have to read and understand books dealing with abstract principles, and to understand those books, they would first have to read other such books, and so on. In short, they would first have to acquire the education they already should have had.

Properly, by the time a student has completed a college education, his brain should hold the essential content of well over a hundred major books on mathematics, science, history, literature, and philosophy, and do so in a form that is well organized and integrated, so that he can apply this internalized body of knowledge to his perception of everything in the world around him. He should be in a position to enlarge his knowledge of any subject and to express his thoughts on any subject clearly and logically, both verbally and in writing. Yet, as the result of the miseducation provided today, it is now much more often the case that college graduates fulfill the Romantic ideal of being "simple, uneducated men."

Contemporary education is responsible for the growing prevalence of irrational skepticism. The students subjected to it do not acquire actual knowledge. They have no firm foundation in a base of memorized facts and they have not acquired any solid knowledge of principles because their education has avoided as far as possible the painstaking processes of logical proof and repeated application of principles, which latter constitutes a vital and totally legitimate form of memorization. Such students go through school "by the seat of their pants." They are forever "winging it." And that is how they go through life as adults. It is impossible for them to have genuine understanding of anything that is beyond the realm of their daily experience, and even of that, only on a superficial level. To such people, almost everything must appear as an arbitrary assertion, taken on faith. For their education has made them unfit to understand how things are actually known. Their failure to memorize such things as the multiplication tables in their childhood, makes it impossible for them to understand whatever directly depends on such knowledge, which, in turn, makes it impossible for them to acquire the further knowledge that depends on that knowledge, and so on. With each passing year of their education, they fall further behind.

Ironically, their failure to memorize what it is appropriate to memorize ends up putting them in a position in which to pass examinations, they have no other means than out-of-context memorization—that is, memorization lacking any foundation in logical connection and proof. Because they have never memorized fundamental

facts, and thus have no basis for developing genuine understanding of all that depends on those facts, they are placed in the position in which to pass examinations they must attempt to memorize out-of-context conclusions. It is because of this that a growing proportion of what they learn as the years pass has the status in their minds of arbitrary assertions. They are chronically in the mental state of having no good reason for most or almost all of what they believe. Thus, in their context of actual ignorance masked by pretended knowledge, they are prime targets for irrational skepticism. To them, in their mental state, doubt of everything can only seem perfectly natural.

Such students, such adults, are easy targets for a doctrine such as "environmentalism." They are totally unprepared intellectually to resist any irrational trend and more than willing to leap on the bandwagon of one that caters to their uncertainties and fears. Environmentalism does this by blaming the stresses of their life on the existence of an industrial society and holding out the prospect of an intellectually undemanding and thus seemingly stress-free pastoral existence, one which is allegedly "in harmony with nature."

The destructive work of contemporary education carried on against the development of students' conceptual abilities from the earliest grades on is compounded, as their education advances to the higher grades, by the teaching of a whole collection of irrationalist doctrines that constitute the philosophical substance of contemporary liberal arts education.

Among them, besides irrational skepticism and the recent addition of environmentalism, are collectivism in its various forms of Marxism, racism, nationalism, and feminism; and cultural relativism, determinism, logical positivism, existentialism, linguistic analysis, behaviorism, Freudianism, and Keynesianism.

These doctrines constitute a systematic attack on reason and its role in human life. All the varieties of collectivism deny the free will and rationality of the individual and attribute his ideas, character, and vital interests to his membership in a collective: namely, his membership in an economic class, racial group, nationality, or sex, as the case may be, depending on the specific variety of collectivism. Because they view ideas as determined by group membership, these doctrines deny the very possibility of knowledge. Their further effect is the creation of conflict between members of different groups: for example, between businessmen and wage earners, blacks and whites, English speakers and French speakers, men and women. And, of course, when collectivism becomes the guiding political principle of a country, the results are unmitigated disaster, ranging from impoverishment to mass murder.¹⁰⁵

Determinism, the doctrine that man's actions are con-

trolled by forces beyond his power of choice, denies the very possibility of rational thought being capable of guiding human life and achieving human happiness. Existentialism, the philosophy that man is trapped in a “human condition” of inescapable misery, obviously teaches exactly the same conclusion.

Cultural relativism denies the objective value of modern civilization and thus undercuts students’ valuation not only of it, but also of the technology and science necessary to build such a civilization, and the valuation of human reason itself, which is the ultimate foundation of modern civilization. It also undercuts people’s willingness to work hard to achieve personal values in the context of modern civilization. The doctrine blinds people to the objective value of such marvelous technological advances as automobiles and electric light, and thus further prepares the ground for the sacrifice of modern civilization to such nebulous and, by comparison, utterly trivial values as “unpolluted air.”

Logical positivism denies the possibility of knowing anything with certainty about the real world. Linguistic analysis regards the search for truth as a trivial word game. Behaviorism denies the existence of consciousness. Freudianism regards the conscious mind (the “Ego”) as surrounded by the warring forces of the unconscious mind in the form of the “Id” and the “Superego,” and thus as being incapable of exercising substantial influence on the individual’s behavior. Keynesianism regards wars, earthquakes, and pyramid building as sources of prosperity. It looks to peacetime government budget deficits and inflation of the money supply as a good substitute for these allegedly beneficial phenomena. Its practical effects, as the present-day economy of the United States bears witness, are the erosion of the buying power of money, of credit, of saving and capital accumulation, and of the general standard of living.

Such doctrines, as I say, constitute the philosophical substance of what now passes for a liberal arts education. If one wishes to use the expression “intellectual mainstream,” and borrow for a moment the environmentalists’ alleged concern with the cleanliness of streams and such, these doctrines may justifiably be viewed as intellectual raw sewage comparable to what can be seen bobbing up and down in a dirty river. They and the methodology of contemporary education have totally fouled the “intellectual mainstream.” The kind of education I have described—if it can still be called education, consisting as it does of an unremitting assault on the rational faculty and every rational value—is responsible for the hordes of graduates turned out over the last decades who have had no conception of the meaning and value of the Constitution and history of the United States, of the meaning and value of Western civilization itself, or in-

deed, as we shall see, of the meaning and value of membership in the human race. It has been responsible for the decline in the quality of government in the United States, as, unavoidably, many such miseducated graduates have found their way into the halls of Congress and the state legislatures, and into major offices in all the other branches of government, and, of course, into all the various branches of the news media and publishing. I believe it has even been responsible for the widespread use of drugs, inasmuch as living in the midst of modern civilization with a level of knowledge as meager as that imparted by contemporary education, must be a source of chronic and profound anxiety, urgently calling for relief. To many, drugs may seem to provide that relief.

The “intellectual mainstream” has been at war with the surrounding capitalist society for over a century and a half. Today, the rise of environmentalism, and of feminism and the new racism, on university campuses and elsewhere, makes clear that the contemporary intellectual mainstream is also at war with the wider intellectual tradition of Western civilization as well. Environmentalism denounces Western civilization for extolling man above nature.¹⁰⁶ Feminism and the new racism denounce it as “sexist” and “racist,” the alleged product of white male genes.¹⁰⁷ Contemporary education, despite the existence of individual exceptions, is thus reduced in its essentials to the activities of a clutch of nonentities engaged in a two-front war with the surrounding material civilization of capitalism and with the intellectual heritage of all of Western civilization.

Clearly, as Ayn Rand observed over thirty years ago, “the intellectuals are dead.” And matters have now reached the point where the most urgent task confronting the Western world is to find replacements—“new intellectuals,” who, unlike the alleged intellectuals of today, will be committed to the value of human reason.¹⁰⁸ Unless such intellectuals can be found, and in sufficient number, the world coming into existence before our very eyes will be very much like the one H. G. Wells described in his science fiction story *The Time Machine*. In Wells’ story, set in the far future, the human race has divided into two degenerate branches: the hideous, subterranean Morlocks, who feast on human flesh, and the pretty, surface-dwelling Eloi, who in totally vacuous innocence serve as food for the Morlocks.¹⁰⁹

It is sometimes difficult to avoid believing that, figuratively speaking, as a result of irrationalist philosophy and its inculcation through contemporary education, these degenerate branches of the human race already exist, in the form of the leaders of the environmental movement and those who offer it no resistance or even rush to join it, oblivious to the obvious destruction that awaits them. For it would seem that contemporary education has

resulted in the creation both of monsters and of vast numbers of people so mentally enfeebled and so deprived of even an elementary sense of manhood that they have no wish or capacity to resist the monsters. Almost every day, such people hear open calls for the radical curtailment of energy consumption—*their* energy consumption—and they do not react. They buy bestselling books by environmentalists and read such passages as, “The environmentally sane standard of living for a population our current size would probably be somewhere between that of the average Englishman and of the average Ethiopian—each lives unreasonably.”¹¹⁰ In other words, they read an open declaration by a leading environmentalist that if environmentalism has its way, *their* standard of living would be somewhere between poverty by American standards and outright famine! Again, they do not react. Of course, they do not even react against calls for mass death.

I believe that the reason the masses of people do not respond with outrage against environmentalism is partly the fact that their education has left them unable to take ideas seriously. They hear and read such pronouncements and have the reaction that, like so much of what they were taught in school, the pronouncements do not mean what they say. In addition, and even more important, their education, reinforced by the experience of growing up in a welfare state, has left many of them with a mentality similar to that of small children, who, lacking all knowledge of how wealth is created, sometimes appear to believe that “money grows on trees.” Very many of our contemporaries, almost certainly the overwhelming majority of the rank and file of the environmental movement, believe that the availability of goods is automatic and indestructible, and that they have a corresponding automatic right to goods. For the most part, they have little or no knowledge of history, and even the very best educated among them have absolutely no real knowledge of economic theory. They simply have no conception of the process of creating wealth or what its requirements are. They have absolutely no concept of what a remarkable productive achievement the economic system of the present-day industrial world actually is and that it is capable of being destroyed.

They are not, of course, so incredibly ignorant as to believe that human beings all over the world live as people do in the United States or the other industrial countries, or that even in these countries people have always lived as they now do. And they certainly do not believe that everyone even in the present-day United States lives well. But to the extent that they have any explanation of differences in the standard of living, it centers on the notion of a *distribution* of wealth. There are poor people in America and elsewhere in the world,

they believe, because of “social injustice”—that is, because of an unfair distribution of wealth. And that is the basis on which they explain the lower standard of living of earlier periods, especially the nineteenth century.

Thus, like small children, they believe that automobiles, television sets, and everything else exist automatically, that, in effect, they just grow on trees. Moreover, they believe that these trees, unlike the trees of nature, will always exist, no matter what is done to them, and that, in the absence of “social injustice,” they will always be able to obtain from them all of the goods they now enjoy.

On this basis, they feel free to support the delivery of one blow after another to the economic system—ever more taxes, ever more regulations—in the expectation that they themselves will never suffer as a result of such actions. All that will happen, they believe, is that they will succeed in shaking loose some more goods, or, nowadays, more and more, succeed in putting an end to this or that irritant or annoyance. The only ones ever to suffer, they believe—if anyone ever actually suffers—are rich businessmen.

All of this is an essential part of the intellectual environment in which the ecology movement has flourished. In this intellectual environment, it is perfectly possible for people to proceed as though, for example, the only connection between their lives and the existence of oil companies is that the oil companies contribute to the pollution of beaches, or, with their pipelines, prevent the migration of one or another species of cute, precious animals. It is perfectly possible for them to carry such blindness to the level of economic activity as such, and to believe that the only practical effect of economic activity is “pollution,” and that in stopping economic activity all they will stop is “pollution.”

It is in this way that they are ripe for the remarkable conclusion, described earlier, that the threatening forces of nature are created by us and that we could do better without our material means for dealing with nature than with them. They feel free to abandon industrial civilization in the unstated conviction that if and when it is abandoned, they will still be able to keep essentially all the goods they now enjoy, and in addition will have such benefits as cleaner air, the preservation of assorted cute animals, and the avoidance of such allegedly impending calamities as frighteningly bad weather. Nothing, they believe, will be required of them but some token loss, such as having to sort their garbage for recycling, or to form carpool, which is not so bad, they feel, because it provides new bases for such good things as “sharing” and camaraderie.

Thus, in what may prove to be the greatest tragedy in all of human existence, we see at the end of more than two centuries of man’s most dazzling success, the prolif-

eration of heirs who as adults possess less than the mentalities of children. We see a culture of reason and science being transformed before our very eyes into one which more and more resembles a culture of primitive man.

Only the emergence of a large number of “new intellectuals” prepared to fight against environmentalism and irrationalism and for reason and capitalism can assure that twenty-first-century man will be man in a sense worthy of the name.¹¹¹

The Cultural Devaluation of Man

The popular acceptance of environmentalism is explainable in all of its aspects on the basis of the irrationalism inculcated by the contemporary educational system and the consequent cultural decline of reason.

The cultural decline of reason is what has created the growing hatred and hostility on which environmentalism feeds, as well as the unreasoning fears of its leaders and followers. To the degree that people abandon reason, they must feel terror before reality, because they have no way of dealing with it other than by reason. By the same token, their frustrations mount, since reason is their only means of solving problems and achieving the results they want to achieve. In addition, the abandonment of reason leads to more and more suffering as the result of others’ irrationality, including their use of physical force. Thus, hatred and hostility increase as rationality decreases.

The closely related readiness of people to accept the doctrine of intrinsic values is also a consequence of the growing irrationalism. An “intrinsic value” is a value that one accepts without any reason, without asking questions. It is a “value” designed for people who do what they are told and who do not think. A rational value, in contrast, is a value one accepts only on the basis of understanding how it serves the self-evidently desirable ultimate end that is constituted by one’s own life and happiness.

As was implicit in earlier discussion, along with destroying confidence in science and technology, the rising tide of irrationalism and growing loss of confidence in reason means loss of the philosophical basis of the valuation of man. For reason is man’s fundamental distinguishing attribute and a culture’s view of reason determines its view of man.¹¹² Thus, as a further result of the assault on reason and loss of confidence in it, the philosophical and cultural status of man has been in decline. This decline was evident well before the emergence of environmentalism. It was evident in such phenomena as the acclaim given to the “antihero” in literature, to works of art and sculpture that were grotesque, twisted representations of human beings, and to books describing man in such terms as “the naked ape” or “the trousered ape.” In

the last generation, as the growth of irrationalism has further accelerated and the effects of the process have more and more reached the general public, confidence in the reliability of reason, and thus the philosophical status of man, have declined so far that now virtually no basis is any longer recognized for a radical differentiation between man and animals. This explains why the doctrine of St. Francis of Assisi and the environmentalists concerning the equality between man and animals is now accepted with virtually no opposition. (Indeed, newspaper and television reporting of animal deaths has taken on a tone once reserved for the human victims of airplane crashes and similar tragedies. This was evident, for example, in the reporting of the Exxon-Valdez oil spill in Alaska and later in that of the oil spills in the Persian Gulf caused by Saddam Hussein. Numbers of dead animals and birds were reported in the same tone of tragedy as numbers of human casualties are reported.)

To the environmentalists, and the closely related supporters of “animal rights,” the possession of reason does not seem significant—because they consider reason to be unreliable; indeed, they regard it as a trap and a snare and hate it. With man’s distinctive attribute thus held to be unworthy of special valuation, man himself necessarily appears unworthy of special valuation. Thus, as the environmentalists see matters, they are advocates of a universal brotherhood of all species and all elements of the “environment.” In their eyes, there are, in effect, blacks, caucasians, orientals, giraffes, snail darters, flies, spotted owls, and mountainsides, all with equal rights in the “environmental family.”¹¹³ The assertion of man’s rights above those of any other species or inanimate object is, in their view, a form of racism and Nazism—of “speciesism”—in which man seeks to treat other parts of the brotherhood of nature as concentration camp inmates.¹¹⁴

This trend is directly and powerfully reinforced insofar as people are increasingly unaware that there ever was such a thing as the Age of Reason and what it stood for, and that there existed, and still do exist, philosophers of reason. Furthermore, people increasingly lack the intellectual capacity to acquire even the slightest understanding of what such thinkers have to say. For example, a book written in the eighteenth or nineteenth century is beyond the power of many of today’s college students and recent graduates to read; they think of it as having been written in “old English.” Worst of all, the introspective experience of the growing hordes of such miseducated people does not provide very powerful testimony on behalf of reason or the value of man. Nor does their external behavior, which increasingly incorporates such practices as the use of narcotics. To someone who can barely read, let alone write or even speak coherently,

despite years of schooling, a view of man as a heroic being, if comprehensible at all, must appear to be from another planet. Such people are intellectually far more at home with the animals of the forest than with the man of the Renaissance and the Enlightenment. They fulfill to the letter the ideal of the Romantics.

The environmentalists do not realize that, apart from man, the allegedly beautiful and harmonious "Nature" that they extol is in reality merely a place in which one thing eats another—alive. If man were nothing more than an animal, he would be entitled to act toward the rest of nature in exactly the same way as all other living things act, namely, to use it for no other purpose than as a means of serving his own survival. But man's possession of reason elevates him above the rest of nature. By virtue of it, man has a range of knowledge and awareness incomparably surpassing that of every other species. And with the aid of goods that his reason makes it possible for him to produce, he comes to surpass all other species in virtually every physical respect as well. Thus, with the aid of goods such as automobiles, airplanes, ships and submarines, telescopes and microscopes, radio and radar, and bulldozers and steam shovels, he can outrace any animal, fly higher and faster than any bird, move in water deeper and faster than any fish, and see and hear further and in more detail and exert incomparably greater force than any other living being.

The possession of reason not only elevates man above the rest of nature in the inherent conflict of species for survival. *Within the human race, it also creates a harmony of rational self-interests* by virtue of making all men potential cooperators in the division of labor and thereby enabling each to serve his own self-interests better by living in peace with his fellow men and enjoying the benefits of the exercise of their reason as well as his own.¹¹⁵ Thus, it is man's possession of reason that is the foundation for an objectively demonstrable brotherhood of *man*, and for the respect that each human being should accord every other human being. It is man's possession of reason that is the only basis for the existence of the concept of rights. Rights are precisely the social conditions of existence rational beings require their fellow creatures to acknowledge for the sake of the proper survival of all. The essential such social condition is that others not initiate the use of physical force against the individual. Only on the basis of respect for individual rights can human beings reap the benefits of the operation of each other's motivated intelligence.¹¹⁶ To put this another way, rights are fundamental *utilitarian* principles, with human life and well-being as the standard of what constitutes utility.¹¹⁷

The only proper ethical standpoint is one which, on the basis of man's possession of reason, asserts the har-

mony of the self-interests of human beings and the absolute priority of human life and well-being over that of any lesser species.

It is only in the name of the special value of man that individual rights can be upheld and such evils as racism and Nazism be opposed. The attempt, for example, to introduce the concept of "speciesism" as something akin to racism totally cuts the ground from all genuine opposition to racism. If man had the same status as cockroaches, what possible difference could it make if two beings the equivalent of cockroaches applied for a job, say, and the employer chose one and rejected the other because he had a prejudice in favor of one color of cockroach over another? Racism can only be opposed on the grounds that it is a denial of what the victim is entitled to as a *human being*, namely, among other things, recognition of his achievements and qualifications irrespective of his skin color—i.e., justice. The environmentalists are able to get away with such a concept as "speciesism" only because hardly anyone any longer stops to think of the meaning of words, but reacts to mere sounds and the tone of voice in which they are uttered. To the unthinking, "speciesism" sounds similar to racism in that it purports to attach significance to membership in some kind of category, and when it is uttered with the same tone of condemnation as that used in connection with racism, it sounds as though it must be an equivalent evil.¹¹⁸

When the environmentalists disregard the special status conferred on man by the possession of reason, they do not thereby elevate flies, snail darters, and mountainsides to the level of man, but rather reduce man to the level of those things. If man is regarded as no better than flies, that is how he will be treated—that is how he is treated in every irrational culture.

Indeed, the doctrine of the environmentalists and the animal rights advocates implies nothing less than that *a human being deserves to be killed for killing a fly*—or for walking on grass or for leaving his footprints in the sand. Each of these things—flies, grass, sand—is alleged by the environmentalists to have a right either to life or to its preexisting condition.¹¹⁹ If capital punishment is to be used to defend such an alleged right to life or preexisting condition, then the conclusion follows inescapably that human beings are to be killed for such things. And what if capital punishment is not to be used? Are human beings then to be imprisoned or flogged for the violation of such alleged rights of flies, etc.? If they are not, is there then to be no punishment at all for the violation of such alleged rights? If the violation of such alleged rights is not to be punished, does that mean that there is also to be no punishment for the violation of a human being's right to life? In proclaiming an equality of species and of the "environmental family," environmentalism is not merely

mistaken. It reveals itself as psychopathic.

In this light, one may wish to consider such statements as: “It is an intensely disturbing idea that man should not be the master of all, that other suffering might be just as important. And that individual suffering—animal or human—might be less important than the suffering of species, ecosystems, the planet.”¹²⁰ The reader may find it difficult to distinguish some of the above thoughts from the utterances of a psychopath who, in the process of torturing his victim, declares that the victim’s suffering is “less important than the suffering of species, ecosystems, the planet.” The reader may encounter similar difficulties in differentiating these words as well:

To cap his argument, White [Lynn White, the leading environmentalist theologian] even dared to defend the rights of life-forms undeniably hostile to his own species, like the smallpox virus, *Variola*. . . . The implication was that a thoroughgoing Christian sense of morality must include smallpox, just as St. Francis included man-eating wolves. Perhaps White hoped for a latter-day saint who could instruct *Variola* in cosmic courtesy. More likely, he simply recognized that in killing people the smallpox virus was only performing its appointed role in the eco-system God created.¹²¹

Of course, these words cannot actually be psychopathic. After all, if they were, such prestigious publishers as Random House and the University of Wisconsin Press could not possibly have published them. Could they? Furthermore, how could anyone object to the teachings of those who “love” so much that they love the enemies of man, and love man fully as much as they love wastelands, ferocious beasts, and vermin?

Contrary to the environmentalists, man and man alone introduces conscious purpose and the perception of order and harmony into the world, and is the source of all value to himself. All of these concepts center entirely on his furtherance, fulfillment, and enjoyment of his life. Man and man alone is capable of having purposes, and must have them if he is to live, since he can live only by means of thinking, planning, and acting on a long-range basis.¹²² The perception of order and harmony comes into the world as man comes to understand the world and how to use that understanding to serve his life. In the process of serving his life, man gives value to nature and to other species of life, as means of serving his life. Always, he is the center and the source of all value and purpose and of the perception of order and harmony.

Of course, the members of other species may be presumed to be of value to themselves, in that they act to survive. However, insofar as their survival clashes with any human value, conflict exists between them and man, and man must—deserves to—prevail. The standard of man’s values is *man’s* life. All presumed other standards of value may be safely left to other forms of life, to

represent them as best they can.

Regrettably, large numbers of our contemporaries apparently have so little self-esteem that it appears sufficient to them merely to assert the existence of any kind of will or value seeking that is contrary to their own and they are prepared to abandon their own values. Thus, there are growing numbers of people who abstain from wearing furs or eating meat out of deference to the desire of lower animals to go on living. Such people value themselves and the enhancement of their own lives below the lives of lower animals. They place their own value not only below that of the lower animals whose furs they might wear or whose flesh they might eat, but also below the value that lower animals attach to themselves. That is, they accord less value to themselves relative to lower animals than all the animals that hunt accord to themselves relative to other lower animals. A lion or leopard values himself above a zebra or gazelle. But the environmentalists and advocates of animal rights value themselves below cattle and sheep and as less worthy of enjoying cattle and sheep than lions and leopards. The logically consistent expression of their view is that of McKibben and White, which calls for surrender to suffering and disease.

True enough, the environmentalists do not always put it this way. What they often say is something along the lines that because man is higher than the animals his behavior must be better than theirs—that, in effect, he must become their benevolent keeper. In other words, the human race is to become a kind of Mother Teresa to the lower animals. This is altruism at the very bottom of the pit. Man, the being who can reach the stars, is to sacrifice his ascent to the heavens for the sake of animals who cannot rise from the mud, and this is how he is to be better than them. Exactly the same point applies to the nonsensical claim that the role of human beings is to serve as “stewards” of the animal kingdom and of inanimate matter, as though the highest creature on earth existed for the sake of the lowest and of inanimate matter.¹²³

To be sure, in serving his own life, man may extend the hand of a form of friendship to members of such species as cats and dogs, which in some ways resemble small children and which typically respond to him with what can only be described as joy and love. Indeed, the love people feel for such friendly creatures may provide a basis for overcoming the growing lunacy of animal rights. Whoever loves a dog, for example, should think of his dog’s pleasure in chewing on a steak bone, say, and ask himself if he does not, after all, value his dog’s pleasure above the life of the cow that provided the steak bone. And then he should ask if this is not perfectly right in view of the fact that the dog is capable of recognizing and responding to him with love, while the cow is little

more than an object, whose greatest contribution to human life and well-being is to serve as a source of milk, meat, and leather. Finally, he should ask himself if it is not also perfectly right that while his dog chews on the steak bone, he, the man, eats the steak itself because he values his own pleasure even more highly than that of his dog.

It is worth noting here that a frequent tactic of the environmentalists in promoting the notion of animal rights is to depict all animals as the equivalent of loving and adorable pets which man somehow viciously chooses to hunt down and terrorize. Amazingly, one environmentalist television “documentary” attempts to depict grizzly bears as the equivalent of puppies or kittens on the basis of the behavior of a young grizzly cub. It casually neglects the fact that an adult grizzly is a terror to man and, incidentally, to cats and dogs.

The producers of such “documentaries” also casually show wild jungle cats terrifying weaker animals and actually eating them alive—animals whom their cameramen, being present on the scene, might have saved from such brutality. At the same time, they and the rest of the environmental movement endlessly berate man for his killing of animals that are not conscious of their fate and that, if necessary, he renders unconscious before killing, as, for example, seal pups. (It should not be necessary to say that the fact that in such cases typically a small number of human beings kills animals on a vastly larger scale than is the case in the animal kingdom itself is a

reflection of the existence of the division of labor, not of wanton, pointless killing. Those who work as seal hunters and so forth, act on behalf of the enormously larger number of people who consume the products the animals make possible.) Surely, even if human beings were no better than lions or leopards, an individual human being would have as much right to the skin of a seal as a lion or leopard has to the flesh of a gazelle. But human beings are incomparably better, more efficient in serving their needs, and deserve incomparably more of everything than any animal does.

The environmentalists and the advocates of animal rights need to learn the value of man and of themselves as the possessors of reason. Perhaps if they were to acquire the education they thus far have apparently lacked, they would succeed in learning their own value.

Man—rational man—not only is capable of creating an economic system which can produce an ever rising standard of living, but, precisely because he is rational—because he is man properly so called—also *deserves* such an economic system and all of the marvelous goods it can bring. In this spirit, the twenty-first century should be the century when man begins such great undertakings as the colonization of the solar system. It should not be a century in which he returns to the Dark Ages. It is the intention of every page and every word of this book to make sure that it is the former alternative which prevails.

Notes

1. See above, pp. 39–41. Most of this section previously appeared in my book *The Government Against the Economy* (Ottawa, Ill.: Jameson Books, 1979), pp. 15–19.

2. In recent years, considerable progress has been made in reducing the costs of extracting oil from tar sands, to the point where such oil now accounts for approximately one-fourth of Canada’s annual production of crude oil. The recoverable oil from the deposits in Alberta alone is estimated to be 300 billion barrels, versus 265 billion barrels estimated for Saudi Arabia. See *New York Times*, December 28, 1994, p. C5.

3. See below, pp. 123–128, for an explanation of how the division of labor provides the framework for continuous economic progress. See also below, pp. 176–180, for an explanation of how, within the framework of a division-of-labor society, the profit motive achieves continuous economic progress, and pp. 622–642, for an explanation of the process of capital accumulation.

4. See Ayn Rand, *Capitalism: The Unknown Ideal* (New York: New American Library, 1966), p. 14.

5. In W. T. Jones, *The Medieval Mind*, vol. 2 of *A History of Western Philosophy*, 2d ed. (New York: Harcourt, Brace, and World, 1969), p. 6.

6. See below, pp. 303–304, for the reasons why government ownership of an industry causes inefficiency.

7. See below, pp. 234–237.

8. “Dismantling of the Shoreham Nuclear Plant Is Completed,” *New York Times*, October 13, 1994, p. B6. See also “New Chapter for Shoreham: New York Files to Take Plant,” *ibid.*, June 29, 1990, p. B3. Remarkably, the environmentalist destroyers of the Shoreham plant attack its owner, the Long Island Lighting company (Lilco), for having high power rates, as though their policies had nothing to do with those rates. It appears, moreover, that Lilco’s acquiescence in its own total elimination has been obtained by a \$9-billion takeover offer from New York State, which is to be financed by the sale of municipal bonds in that amount. If this offer is consummated, it will repeat the pattern previously evident in the government’s takeover of the American railroad industry, namely, first, the government’s destruction of an industry’s or company’s profitability, followed by the comparative relief of socialization at a price that at least provides some measure of compensation. Following an official statement of the takeover offer, which would entail a purchase price of Lilco’s stock at \$21.50 a share, the firm’s stock rose 25 cents to \$17.375 a share on the New York Stock Exchange. (*Wall Street Journal*, Western ed., October 28, 1994, p. A9.)

9. See “Mideast Crisis Puts New Spotlight On an Idle Oil Plant in California,” *New York Times*, September 1, 1990, p. 1.

10. The expression “factors of production” can be understood as synonymous with the expressions “means of production” or “physical elements of production.” As will be seen, in the context of a division-of-labor economy, in which all productive activity is vitally dependent on the earning of money, use of the expressions implicitly requires that the physical goods or services representing the factors of production be purchased for the sake of making subsequent sales. On this point, see below, pp. 442–456.

11. Cf. Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 127–131.

12. See *ibid.*

13. Cf. David Ricardo, *Principles of Political Economy and Taxation*, 3d ed. (London, 1821), chaps. 2 and 3; reprinted as vol. 1 of *The Works and Correspondence of David Ricardo*, ed. Piero Sraffa (Cambridge: Cambridge University Press, 1962).

14. See above, n. 3 of this chapter. See also above, pp. 45–46, and below, 106.

15. For elaboration of this point, see below, pp. 313–316.

16. For elaboration of these propositions, see below, pp. 191–192 and 206–209.

17. Of course, if the property in question were of truly outstanding beauty, it would have greater economic value as a tourist attraction than in any ordinary economic use such as coal mining. All that would be necessary to ensure its use in this capacity would be that it be privately owned. In this way, all possible competing uses would be free to find expression in competing bids to the owner, with the one most highly valued by the consumers thereby being free to outcompete the ones less highly valued by the consumers.

18. Cf. Llewellyn H. Rockwell, “Government Garbage,” *Free Market* 8, no. 2 (February 1990), pp. 2, 8. See also Peter Passell, “The Garbage Problem: It May Be Politics Not Nature,” *New York Times*, February 26, 1991, pp. B5, B7.

19. Rockwell, “Government Garbage.”

20. *Ibid.*

21. Today’s conservationists and environmentalists, of course, have a preference for “biodegradable” garbage, such as decaying animal and vegetable matter, which rots and smells. They prefer this to the inert kind, such as aluminum or styrofoam, which appears to remain in its original condition for an indefinitely long time. The basis of their preference appears to be that they object to the existence of permanent evidence of modern technology and concomitant mass consumption.

22. The last sentence of this paragraph and the next two paragraphs are taken, with a few minor changes, from *The Government Against the Economy*, pp. 19–20.

23. Of course, the essential objection to the policy of conservationism is not strictly that it compels us to perform more labor, though that is almost always true, but that it compels us to expend means of production of greater value to achieve a saving of lesser value. There are cases in which we must expend two or more hours of low-paid labor to save one hour or less of high-paid labor, or many hours of labor to save a quantity of extremely valuable material. The comparative market prices involved determine which is the appropriate course of action. See below, pp. 206–209 and 212, for further explanation of this principle.

24. Cf. Ayn Rand, *Atlas Shrugged* (New York: Random House, 1957), pp. 1012–1013; *The Virtue of Selfishness* (New York:

New American Library, 1964), pp. 1–34.

25. See above, pp. 43–45.

26. See above, pp. 63–66.

27. The destructive government policies I refer to are prounion and minimum-wage legislation, the welfare system, farm subsidies, rent controls, and laws prescribing such things as the number of people who may occupy an apartment or the minimum floor space, window area, and so forth which must exist per occupant. Prounion and minimum-wage legislation deprive people of the opportunity of obtaining employment by making labor artificially more expensive and thus reducing the quantity of it demanded below the supply available. The welfare system eliminates the necessity of being self-supporting and thus of learning the skills necessary to become so and thus the possibility of advancing from there. Farm subsidies make the price of food higher than it would otherwise be. Rent controls create shortages of rental housing by enlarging the quantity of rental housing demanded and reducing the supply available, thereby making it impossible for some people to find housing. Laws prescribing minimum levels of housing amenities have the effect of pricing housing beyond the reach of some people. In the absence of such laws and of rent controls, some amount of housing would be available for and within the financial reach of every working person. For elaboration of all these points, see below, pp. 172–294 *passim*, 580–594, and 655–659.

28. Chapter 4 will show how the invention, production, and application of machinery all depend on the division of labor. See below, pp. 123–128.

29. *New York Times*, May 25, 1992, p. 1.

30. Cf. Ayn Rand, *The New Left: The Anti-Industrial Revolution* (New York: New American Library, 1971).

31. See above, pp. 48–49.

32. An excellent book that refutes most of the specific claims of the environmentalists is Jay Lehr, ed., *Rational Readings on Environmental Concerns* (New York: Van Nostrand Reinhold, 1992). Portions of this chapter, previously published as a pamphlet *The Toxicity of Environmentalism*, appear as the summary to the book.

33. George Reisman, “Education and the Racist Road to Barbarism,” *Intellectual Activist* 5, no. 4 (April 30, 1990), pp. 4–7; reprinted as a pamphlet (Laguna Hills, Calif.: The Jefferson School of Philosophy, Economics, and Psychology, 1992).

34. For a comprehensive discussion of the safety of nuclear power, see Petr Beckmann, *The Health Hazards of Not Going Nuclear* (Boulder, Colo.: Golem Press, 1976).

35. *New York Times*, September 20, 1990, p. A15.

36. For elaboration of this point, see below, pp. 275–278. See also pp. 172–180, for an account of the contrasting operations of capitalism.

37. Carl Sagan, “Tomorrow’s Energy,” *Parade*, November 25, 1990, p. 10.

38. *Ibid.*, p. 11.

39. It should be realized that it is no answer to this fact to point to cases in which the loss of energy may appear to be compensated for by a change in the kind of equipment or materials used—for example, obtaining the same illumination, despite the consumption of less electricity, by means of using specially designed lamps. By their nature, cases of this kind entail greater costs. If they did not, there would be no need for the conservationists to urge, let alone attempt to compel, the adoption of

such things. The significance of the higher costs is that less wealth is available for other purposes. Thus, conservation provides energy for one use only by depriving people of energy needed for other uses and, in provoking their efforts to compensate for this loss, may well deprive them of wealth required for other purposes.

40. *Los Angeles Times Book Review*, Sunday, October 22, 1989, p. 9.

41. Bill McKibben, *The End of Nature* (New York: Random House, 1989), p. 176.

42. Another example is that of Christopher Manes, the author of *Green Rage: Radical Environmentalism and the Unmaking of Civilization* (Boston: Little, Brown, 1990). He and the Earth First! organization he supports regard famine in Africa and the spread of AIDS as environmentally beneficial developments. The founder of Earth First!, David Foreman, has described mankind "as a cancer on nature," and has said, "I am the antibody" (in *New York Times Book Review*, Sunday, July 29, 1990, p. 22). Another representative of Earth First! writes: "Only a very few of human pathogens are shared by other partners on our planet. Biological warfare will have no impact on other creatures, big or small, if we design it carefully" (in *Forbes*, October 29, 1990, pp. 96–97). And Paul Ehrlich, one of the oldest and most prominent leaders of the environmental movement, who is supposedly entirely respectable, criticizes the "preoccupation with death control," by which he means, "preoccupation with the problems and diseases of middle age." In his view, such preoccupation, and its consequent lengthening of human life expectancy, "will lead to disaster." (Ehrlich, *The Population Bomb* [New York: Ballantine Books, 1968], p. 91).

43. *New York Times*, August 30, 1990, pp. A1, C15.

44. The alleged danger of radiation is not a valid objection to atomic power. The radiation emission of an atomic power plant located next door to one's house is equal to about two percent of the radioactivity one normally receives from all other—almost entirely natural—sources. On this point, see Beckmann, *Health Hazards*, pp. 112–113. Nor are the alleged dangers of storing atomic wastes a valid objection. Nature itself has always stored such highly radioactive elements as radium and uranium without significant danger to human life.

45. See above, p. 75.

46. In the case of whales, domestication might be feasible if the establishment of electronically fenced ocean "ranches" were allowed and if some part of the existing population of whales could be made private property. In the case of the buffalo, it appears that to a modest extent they now are raised commercially.

56. Cf. Ames, "Major Carcinogens," pp. 243–244.

57. See "No Evidence of Global Warming in 1980's Is Detected by Satellites," *New York Times*, March 30, 1990.

58. *Ibid.*, December 13, 1989, p. A18. See also Lehr, *Rational Readings on Environmental Concerns*, pp. 393–437.

59. Ehrlich, *Population Bomb*, p. 61.

60. Cf. McKibben, *End of Nature*, p. 111.

61. See "Scientists Warn of Dangers in a Warming Earth," *New York Times*, May 26, 1990.

62. *Ibid.*

63. See below, Chapter 6, especially pp. 209–211 and 212.

64. On the operations of the price system and the vital role it plays in genuine economic planning—that is, the economic planning of private individuals and business—see below, pp. 137–139 and 172–294 *passim*.

65. The process of rational reform would be greatly accelerated, if students from such countries, when attending universities in the United States, were taught the virtues of capitalism rather than Marxist propaganda.

66. On these points, see *New York Times*, January 16, 1990, p. C1, and *ibid.*, September 18, 1990, p. B5.

67. See *ibid.*, December 13, 1989, p. A18.

68. The ecologists, of course, denounce it, on the grounds that it destroys various plant and animal species and contributes to global warming through destroying forests. They also claim that after the land has been cleared and the existing soil nutrients are exhausted, the land becomes desert. In answer to this last, they have apparently never heard of the Atherton tablelands in Australia, which were originally jungle and which are now, and for many years have been, beautiful and thriving farmland. Nor, apparently, do they take into account the ability to replenish soil nutrients through the use of chemical fertilizers.

69. McKibben, *End of Nature*, p. 170. Italics mine.

70. Nature, to be sure, does not produce anything directly comparable to traffic congestion, but it does produce all manner of obstacles in the way of travel, such as forests, rivers, and mountains. Thus, traffic congestion is abstractly comparable to nature's obstacles to travel.

71. Of course, it would be possible for the owners of surrounding land at some later time to buy back this right. This would occur in cases in which the increase in the value of their land once free of the negative effects caused by the present producer outweighed the value to that producer of continuing his present operations. In such cases, the owners of the surrounding land would be able to offer him a price that made the surrender of his previously acquired right financially worthwhile.

72. The fall in prices relative to incomes that economic progress achieves is, of course, present when incomes rise faster than prices, which is the way the phenomenon is experienced when accompanied by inflation of the money supply. On the subject of how real incomes rise, see below, pp. 176–180. See also pp. 618–622 and 655–659.

73. Letter signed by Michael L. Fisher is undated (but appeared sometime in 1990), p. 3. Emphasis his.

74. Exactly the same practice, it is worth noting, was followed by the administration of former Governor Jerry Brown of California, which argued that oil fields off a certain portion of the state's coast should not be developed because they would provide the nation as a whole with only a ten-day supply of oil.

75. Carl Sagan, "Tomorrow's Energy," p. 10.

76. For an exposition of the doctrine, see Paul Samuelson and William Nordhaus, *Economics*, 13th ed. (New York: McGraw-Hill, 1989), pp. 770–775.

77. It is worth noting that in a division-of-labor, capitalist society everyone normally does *earn* his standard of living, even people of average and below average ability. But he earns it very easily. The essential thing that is required of the great majority of people is merely the expenditure of the mental effort required to learn the new skills made necessary by the work of the innovators. Thus, someone with the muscles and brawn of a caveman, or a blacksmith, is enabled to enjoy a standard of living that includes such things as automobiles and television sets, merely by being willing to acquire an elementary education, to learn some new skills throughout his life when others introduce further advances, and, above all, to respect the rights of such others to their greater gains. For elaboration on the economic position of the average person under capitalism, see in particular Chapters 9 and 14, below.

78. For a further critique of the externalities doctrine, in particular the external-benefits doctrine, see below, pp. 335–336.

79. For a full account of how the environmental movement, in conjunction with the U.S. government, has been responsible not only for the high price of oil and oil products but also for virtually every other aspect of the energy crisis, see above, pp. 66–67 and 172–264 *passim*, but especially pp. 234–237.

80. These principles were clearly understood both by the U.S. Federal Appeals Court for the District of Columbia Circuit and by the U.S. government's Office of Management and Budget under the Bush administration. The Court cited research demonstrating that one additional death may result from reduced incomes caused by each \$7.5 million of additional expense imposed by government regulation. On this basis, the Office of Management and Budget blocked the enactment of a costly set of environmental regulations proposed by the Department of Labor which ostensibly sought to promote workers' health and safety. The Office found that the regulations were so expensive that their enactment would cause more deaths than they would avoid. See "Citing Cost, Budget Office Blocks Workplace Health Proposal," *New York Times*, March 16, 1992, p. A13.

81. For elaboration of the principles involved in the present discussion, see below, pp. 622–642.

82. "Marsh Destroyed, Owner Is Fined," *New York Times*, May 26, 1990.

83. The law of comparative advantage is explained on pp. 350–356. The doctrine of the harmony of interests is demonstrated in almost every chapter of this book, but see especially Chapters 6, 9, 11, 13, and 14.

84. See above, pp. 35–36.

85. Barry Commoner, *The Poverty of Power* (New York: Alfred A. Knopf, 1976), pp. 252, 254. For a refutation of all aspects of the Marxian exploitation theory, see below, pp. 473–498 and 613–666.

86. If the influence of the ecology movement continues to grow,

then it is perfectly conceivable that in years to come, the very intention of a country to increase its production could serve as a cause of war, perhaps precipitating the dispatch of a U.N. security force to stop it. Even the mere advocacy of economic freedom within the borders of a country would logically—from the depraved perspective of the ecology movement—be regarded as a threat to mankind. It is, therefore, essential that the United States absolutely refuse to sanction in any way any form of international limitations on "pollution"—that is, on production.

87. Cf. Brad Erickson, ed., *Call to Action, Handbook for Ecology, Peace and Justice* (San Francisco: Sierra Club Books, 1990), p. 5.

88. See, for example, Kirkpatrick Sale, *Dwellers in the Land* (San Francisco: Sierra Club Books, 1985). This book is marked by total ignorance of history and of every proposition of economics.

89. Cf. Ayn Rand, "The Left: Old and New," in Ayn Rand, *The New Left*.

90. The costs merely of complying with the environmental movement's demands for the cleanup of toxic waste sites is estimated at between \$300 billion and \$700 billion over the coming few years. See "Experts Question Staggering Costs of Toxic Cleanups," *New York Times*, September 1, 1991, p. 1. (The cost of complying with other antipollution regulations is currently \$115 billion per year. [*Ibid.*, p. 12.]) Even using the EPA's far-fetched methods of estimating risk, the maximum number of cancer cases which can be linked to public exposure to hazardous wastes is approximately 1,000 per year. (*Ibid.*) All reasonable protection against such wastes can frequently be secured for as little as one-half of one percent of the costs presently mandated by law and by the EPA. (*Ibid.*) Thus, hundreds of billions of dollars have been and are to be squandered to appease the imaginary terrors of the environmentalists.

91. On the nature of altruism and self-sacrifice, see Ayn Rand, *Atlas Shrugged and Virtue of Selfishness*.

92. Cf. F. A. Hayek, *The Fatal Conceit: The Errors of Socialism*, W. W. Bartley III, ed. (London: Routledge, 1988).

93. See above, pp. 19–36.

94. See above, pp. 35–36.

95. I am indebted for this vital distinction to von Mises. It was an observation he made in his seminar at New York University.

96. This proposition bears an essential similarity to the theory of capital accumulation presented below on pp. 622–642.

97. Thalidomide, of course, was the drug that was prescribed as a tranquilizer for pregnant women and that turned out to cause major damage to fetuses.

98. On these points, see the article of Leonard Peikoff, "Maybe You're Wrong," *Objectivist Forum* 2, no. 2 (April 1981), pp. 8–12.

99. See Ayn Rand, *Introduction to Objectivist Epistemology*, 2d ed. enl., ed. Harry Binswanger and Leonard Peikoff (New York: New American Library, 1990), pp. 77–82.

102. Ayn Rand, *Objectivist Epistemology*, p. 81.

103. Jones, *Kant*, p. 102.

104. *Ibid.*, p. 104.

105. See below, Chapter 8 passim.

106. For example, McKibben writes: “Perhaps the ten [sic] thousand years of our encroaching, defiant civilization, an eternity to us and a yawn to the rocks around us, could give way to ten [sic] thousand years of humble civilization, when we choose to pay more for the benefits of nature, when we rebuild the sense of wonder and sanctity that could protect the natural world.” (McKibben, *End of Nature*, p. 215.) According to this passage, the ten thousand years in which man has risen from the cave and which embrace the totality of man’s civilization were a mistake—they were “encroaching, defiant.” In the next ten thousand years, McKibben hopes, the wildlife, the weeds, and the rock formations that constitute nature will be protected from us, because we will have abandoned anything resembling Western civilization.

107. On the new racism and its hostility to Western civilization, see my essay “Education and the Racist Road to Barbarism.”

108. See Ayn Rand, *For the New Intellectual* (New York: Random House, 1961) p. 67.

109. See H. G. Wells, *The Time Machine* (London, 1895); reprinted in *Treasury of World Masterpieces: H. G. Wells* (New York: Octopus Books, 1982.)

110. McKibben, *End of Nature*, p. 202.

111. An essential requirement of becoming such a “new intellectual” is, of course, to read and understand the works of Ayn Rand, Ludwig von Mises, and the British classical and Austrian economists, as well as the political philosophy of John Locke and the Founding Fathers of the United States. The importance of all of these works was explained above, in the Introduction to this book. In addition, a thorough knowledge of history and extensive reading of the great classics of literature and philosophy, as well as familiarity with mathematics and natural science at what used to be the college level, are also requisite. In other words, to be a “new intellectual,” one must have an education similar in kind to that which intellectuals used to have, plus be thoroughly familiar with the philosophy of Objectivism, the writings of von Mises, classical and Austrian economics, and the political philosophy on which the United States was established.

112. See above, pp. 19–21.

113. It is interesting to recall here some previously quoted words of Graber, whose implications I did not develop at the time: “I, for one, cannot wish upon either my children or the rest of Earth’s biota. . . .” The philosophical meaning of these words is that Graber sees no fundamental distinction, requiring separate classification, between his own children and flies and earthworms.

114. The term *speciesism* appears, among other places, in Roderick Frazier Nash, *The Rights of Nature* (Madison, Wis.: University of Wisconsin Press, 1989) pp. 5, 138, 142, 153. This book is impregnable against all arguments falling in the category of *reductio ad absurdum* inasmuch as it enthusiastically supports almost every imaginable absurdity that is present in the doctrine of animal rights. For example, it states, approvingly: “The ecologist noted that smallpox, as part of the biotic community, was a product of evolution as were wolves and

whales and redwood trees. According to the biocentric reading of environmental ethics, there was no logical reason for discriminating against the virus just because it was small and harmful to humans” (p. 85). Interestingly, the author pretends throughout to be a fervent supporter of John Locke and the doctrine of natural rights. Yet at no point in his book is there a discussion of the connection between human reason and rights or of the proreason, proman context in which John Locke wrote. The word *reason* does not even appear in the book’s index. Although publication of such a philosophically disgraceful book by a university press should not be surprising in today’s environment, it should still provoke outrage.

115. See below, Chapter 4. See also von Mises, *Human Action*, pp. 143–176 on the nature of human society, and below, Chapter 9 passim.

116. Cf. Ayn Rand, “Man’s Rights,” in *Virtue of Selfishness*; and the discussion of rights in *Atlas Shrugged*, pp. 1061–1063.

117. This observation, of course, has bearing on the dispute between those defenders of capitalism who support the doctrine of natural rights and those who describe themselves as utilitarians. If rights are understood in the context of taking man’s life as the standard of useful action, there need be no conflict.

118. Interestingly, exactly the same kind of process of lack of thought has resulted in the term “discrimination” becoming one of opprobrium. It is perfectly proper, in fact absolutely necessary to human survival, to discriminate between food and poison, between tigers and pussycats, between danger and the lack of danger. What is not proper is to ignore an individual’s achievements and superior qualifications because of his racial membership. Such behavior represents a failure to discriminate on the basis of fundamentals—namely, what the individual has accomplished—in favor of discriminating on the basis of a triviality, namely, his mere racial membership. It is to deny credit to the individual for what is within his power, while condemning him for what is not in his power. It is for this reason that discrimination based on race is wrong. But today’s unthinking mentalities hear the word “discrimination” uttered with condemnation and then believe that any form of discrimination is evil, including discrimination in favor of the competent over the incompetent.

119. “I am quite seriously proposing that we give legal rights to forests, oceans, rivers and other so-called ‘natural objects’ in the environment—indeed, to the natural environment as a whole.” (Christopher D. Stone, a University of Southern California law professor in Nash, *Rights of Nature*, p. 121. Stone argued this position before the U.S. Supreme Court with the support of the Sierra Club. His views were endorsed by Justice Douglas. [*Ibid.*, pp. 128–131].)

120. McKibben, *End of Nature*, p. 182.

121. Nash, *Rights of Nature*, p. 95.

122. Cf. Ayn Rand, *Virtue of Selfishness*, pp. 11–16.

123. People can, of course, legitimately be concerned with the avoidance of unnecessary cruelty to animals. Much more importantly, they can legitimately be concerned with the avoidance of unnecessary suffering on the part of their fellow human beings. The proper course for those who truly are concerned with eliminating unnecessary human suffering is not to immolate themselves, but, first and foremost, to support capitalism and its underlying philosophy and economic theory, and, no

less, to pursue their own rational self-interest. For elaboration see below, pp. 332–335, and above, n. 111, which provides a list of the major philosophical and theoretical sources in defense of capitalism. Practically the whole of this book is a demonstration of how the pursuit of rational self-interest operates to the interest of all. Long before the reader reaches the end of this book, it should be overwhelmingly clear to him, if he has read with any significant degree of understanding, how the self-interested activities of businessmen and capitalists accom-

plish far more economic benefit for the poor, and thereby alleviate far more suffering and hardship, than the work of the most devout practitioners of self-sacrifice and charity ever has accomplished or ever could accomplish. These results, of course, are not the motive of the businessmen's and capitalists' activities—selfish profit is the motive—but they are the necessary, inevitable effect of those activities, provided only that the businessmen and capitalists are left free to pursue their profit and thus to carry on their activities.

PART TWO
THE DIVISION OF LABOR AND CAPITALISM

CHAPTER 4

THE DIVISION OF LABOR AND PRODUCTION

1. The Division of Labor and the Productivity of Labor

Human life and well-being depend on the production of wealth. The production of wealth vitally depends on the division of labor, that is, a system of production in which the labor required to support human life and well-being is broken down into separate, distinct occupations. As we have seen, under a system of division of labor, the individual lives by producing, or helping to produce, just one thing or at most a very few things, and is supplied by the labor of others for the far greater part of his needs.

The division of labor raises the productivity of labor in six major ways, and thereby achieves a radical increase in the efficiency with which man is able to apply his mind, his body, and his nature-given environment to production.

It increases the amount of knowledge used in production by a multiple that corresponds to the number of distinct specializations and subspecializations of employment. This makes possible the production of products and the adoption of methods of production that would otherwise be impossible.

It makes it possible for geniuses to specialize in science, invention, and the organization and direction of the productive activity of others, thereby further and progressively increasing the knowledge used in production.

It enables individuals at all levels of ability to concentrate on the kind of work for which they are best suited on the basis of differences in their intellectual and bodily endowments.

It enables the various regions of the world to concentrate on producing the crops and minerals for which they are best suited on the basis of differing conditions of climate and geology.

It increases the efficiency of the processes of learning and motion that are entailed in production.

It underlies the use of machinery in production.

The Multiplication of Knowledge

To understand how the division of labor represents a multiplication of the knowledge used in production, it is only necessary to realize that in a division-of-labor society, such as our own, there are as many distinct bodies of knowledge used in production as there are distinct specializations and subspecializations of employment. Steel producers, for example, have a different body of knowledge from that of auto producers. Wheat farmers have a different body of knowledge from both of these and even from that of other farmers, such as vegetable growers or dairy farmers. The bodies of knowledge of all such specializations enter into the process of production in a division-of-labor society, and each individual is enabled to obtain products reflecting the total of such knowledge. Thus, steel producers give the benefit of their knowledge to the whole rest of society; in return, they are able to receive from the rest of society the benefit of the specialized knowledge held by all other categories of producers. And so it is with the members of every specialization.

This is a result of enormous importance, and its significance needs to be carefully considered. What a division-of-labor society represents is *the organization of the*

same total sum of human brain power in a way that enables it to store and use vastly more knowledge than would otherwise be possible.

To grasp this point fully, we must consider the contrasting case of a non-division-of-labor society, such as exists in most of Asia, Africa, and Latin America. In those areas, where the overwhelming majority of people live as virtually self-sufficient farmers, each family knows essentially what all the others know about production. To confirm this fact, one might imagine an effort to compile all the knowledge entering into production in such places. One might imagine a corps of interviewers who obtain a grant from the U.S. government to go out and write down all that the rural farm families of these areas know about production. After interviewing the first such family in each area, very little additional information would be gained from interviewing the hundreds of millions of other such families. What this means, in essence, is that the sum total of the knowledge used in production in a non-division-of-labor society is limited to what the brain of just one or two individuals can hold. Any one farmer, or farmer plus his wife, in those areas holds practically all of the knowledge that is used in production in the entire society.

To put it mildly, such a situation is a case of wasteful duplication. It is the wasteful duplication of the mental contents of the human brain—the wasteful use of man’s ability to store and use knowledge. In this respect and in this sense, a division-of-labor society is indispensable to the efficient use of the human mind in production. To the degree that production is divided into separate specializations, with separate bodies of knowledge, the same total of human brain power is enabled to store and use more knowledge, to the benefit of each and every individual member of that society. This is the meaning of the proposition that the division of labor represents the multiplication of the knowledge used in production. It multiplies such knowledge to the degree that specializations and specialized bodies of knowledge exist. And it multiplies correspondingly the benefits that man is able to derive from the use of his mind.

The enlarged body of knowledge that a division-of-labor society makes possible is the precondition for producing products and adopting methods of production that require more knowledge than any one person, family, village, or tribe can possess. To illustrate this fact and be able to appreciate its importance, let us consider the amount of knowledge required to produce a relatively simple product, such as a ballpoint pen, which almost everyone uses practically every day in our society.

To make the pen, far more knowledge is required than is possessed by the producers of the pen. They can begin with the purchase of plastic, ink, pen points, and various

types of machinery. What they know is how to produce such pens from this stage on. But others must know how to produce the plastic, the ink, the points, and the equipment. Still others must know how to produce the petrochemicals, from which the plastic comes; the various chemicals from which the ink is made; the metals from which the points are produced; and the components for the equipment.

At further stages of remove from the pen, yet still others must know how to refine petroleum, how to explore for it, drill for it, and store and transport it; how to produce the drilling and refining equipment, the parts and materials to make that equipment, and so on. Tracing now the chemicals for the ink, the metals for the points, and the components for the pen-making equipment further back, we are led into the chemical industry, the mining industry, and the machine tool industry. At practically all stages, we encounter the construction industry, which had to erect the various factories involved; the electric power industry, which provides the factories and machines with light and power; and the transportation industry, which moves the various products and means of production to where they are required. And these industries lead us back to the industries producing the materials and equipment they in turn require.

We find that the production of a seemingly simple product like a ballpoint pen is not so simple after all. It is closely tied to the production of most of the rest of the economic system in a virtual spider web of complexity, with threads running back and across to almost every other branch of industry in ways that are too complex even to be completely and accurately *named* by anyone, let alone actually understood in the way required for production. This “simple” product is the result of vastly more knowledge applied to production than any one individual, family, village, or tribe could ever hope to acquire.

A division-of-labor society is obviously indispensable for the production of all the wonderful products introduced over the last two centuries, from steam engines to rocketships. By the same token, it is equally indispensable for the ability to use modern, efficient methods of production in making goods that can be produced in modest quantities with little or no division of labor—for example, being able to use tractors and chemical fertilizers to help produce wheat.

The Benefit from Geniuses

Closely related to the multiplication of the knowledge used in production is the fact that the division of labor makes possible a radical and progressive increase in the benefit derived from the existence of geniuses. In the absence of a division-of-labor society, geniuses, along

with everyone else, must pass their lives in producing their own food, clothing, and shelter—assuming they are fortunate enough to have survived in the first place. Perhaps their high intelligence enables them to produce these goods somewhat more efficiently than do other people. But their real potential is obviously lost—both to themselves and to the rest of society.

In contrast, in a division-of-labor society geniuses are able to devote their time to science, invention, and the organization and direction of the productive activity of others. Instead of being lost in obscurity, they become the Newtons, the Edisons, and the Fords of the world, thereby incalculably raising the productivity of every member of the division-of-labor society.

The effect of a division-of-labor society is thus not only to increase the total of the knowledge that the same amount of human brain power can store and use, but *also to bring that knowledge up to a standard set by the most intelligent members of the society*. The average and below-average member of a division-of-labor society is enabled to produce on the strength of the intelligence of the most intelligent. Thus, in a division-of-labor society, people even of minimal intelligence are enabled to produce and obtain such goods as automobiles and television sets—goods which on their own they would not even have been able to imagine.

And in each succeeding generation, geniuses are able to begin with the knowledge acquired by all the preceding generations, and then make their own, fresh contributions to knowledge. In this way, the knowledge and productive power of a division-of-labor society are able progressively to increase, reaching greater and greater heights as time goes on.

Concentration on the Individual's Advantages

In a division-of-labor society, not only productive geniuses, but everyone is enabled to concentrate on the kind of work for which he is best suited by virtue of his intellectual and bodily endowment. This principle applies to artistic and musical geniuses, to individuals with the kind of rare talents required to perform surgical operations or to be a champion athlete, on down to people whose special advantage may consist merely of such attributes as the possession of relatively keen eyesight or relatively great physical strength.

As with productive geniuses, those with the potential ability to be great artists or musicians, great surgeons or athletes, or outstanding creators or performers of any kind, would not be able to realize their potential in the absence of a division-of-labor society. Because even if they managed to be born and reach adulthood, their time would be taken up with growing their own food and making their own clothing and shelter. In a division-of-

labor society, on the other hand, such individuals can realize their potential. And all the rest of mankind gains from it—from being able to enjoy the art and music they create, from being able to live because of the surgical operations they perform, and from being able to have the pleasure of observing the feats they accomplish.

In a division-of-labor society, *every* productive advantage that individuals possess tends to be put to use and to raise the productivity of labor. Imagine, for example, the case of just two people: Robinson Crusoe and Friday. Assume that Crusoe is particularly skillful in fishing, but not very skillful in hunting. Assume that with Friday, it's just the opposite: he is very skillful in hunting, but not particularly skillful in fishing. To make the case more concrete, imagine that it takes Crusoe 1 day to catch 10 salmon, and 2 days to hunt a deer; while Friday requires 2 days to catch 10 salmon, but only 1 day to hunt a deer. If the two men work independently of each other, without dividing labor, then in 3 days each will have caught 10 salmon and hunted 1 deer. Their combined output will be 20 salmon and 2 deer. But if they divide labor, with Crusoe concentrating on fishing, and Friday on hunting, then in exactly the same time, their combined output will be 30 salmon and 3 deer—that is, 50 percent more. For in 3 days Crusoe can catch 30 salmon, while Friday can hunt 3 deer.

In a society of millions, hundreds of millions, or however many people, each person tends to concentrate on the specific things for which he is intellectually and physically best suited. And thus the production of everything tends to be carried on in the most efficient way it can be carried on in the circumstances. The production of everything tends to be carried on by those who can do it relatively best.

Geographical Specialization

A special aspect of individuals concentrating on what they do best is the more efficient utilization of land and natural resources. What an individual does best depends not only on his intellectual and bodily endowments, but also on the external conditions of nature that confront him. An individual living in a tropical climate, say, is able to grow tropical fruits or vegetables far more easily than someone living in a temperate climate, if the latter can grow them at all. An individual living close to rich deposits of iron ore, say, is able to mine such ore far more easily than someone not living close to such deposits, if the latter can mine iron ore at all.

Thus, a major aspect of the gains provided by the division of labor is that it raises the productivity of labor in the exploitation of land and natural resources. For what many people do best and are led to concentrate on is precisely the exploitation of advantages afforded them

by climate and by their proximity to special types of land and natural resources.

The result of specialization along these lines is that every geographical area can obtain products that depend on the special advantages of other areas. Each area that possesses special advantages concentrates on those advantages to some degree and produces more of the products in question than its own inhabitants consume. The difference is exchanged for the products of other areas, which possess different advantages. The effect is that every area can obtain the benefit of the special advantages of every other area. Thus, the people of the whole United States can be supplied with iron ore from Minnesota, coal from Pennsylvania, oil from Texas, wheat from Kansas, corn from Iowa, and oranges from Florida. And, of course, the gains are international: the whole world can benefit from Brazil's advantages in coffee growing, Saudi Arabia's oil deposits, and the advantages of the various American states just described.

Furthermore, the ability of each area to exploit its own advantages vitally depends on its incorporation into the division of labor. For example, very little iron ore could be smelted without coal to provide fuel. By the same token, very little coal could be mined without iron and steel to make possible the production of the necessary equipment. The exploitation of every natural resource is enormously improved by virtue of access to the resources of other areas.

Economies of Learning and Motion

The division of labor increases the efficiency of the processes of learning and motion that are entailed in production.

First, under the division of labor, the individual who learns an occupation is able to apply his learning repeatedly, because he devotes his full working time to that occupation. The effect of this repetition is that he becomes extremely proficient in the use of his knowledge. In effect, he subconsciously automatizes the knowledge—he learns it so well that he no longer has to think things out step by step, as one does before one has the necessary experience or after one has been away from a field for a long time. A worker who is constantly practiced in his work can obviously accomplish a great deal more in the same time than one who is not. Outside the division of labor, on the other hand, even in cases in which people might be able to acquire sufficient knowledge to accomplish something, they would most likely not have sufficient occasion to use that knowledge to become proficient in its use.

A good example of this, drawn from the context of our own society, is the case of a professional repairman versus a do-it-yourself homeowner. A good professional plumber, say, can usually spot the source of a plumbing

problem very quickly, decide exactly what needs to be done, reach for the appropriate tools and supplies, and do it. The inexperienced homeowner, on the other hand, who tries to repair his own plumbing, must probably first read a book about how to do it, and then, assuming he has correctly diagnosed the problem and obtained all the necessary tools and supplies, fumble about trying to do it. Even if, later on, he needs to make the same repair again, the homeowner will probably experience many of his original difficulties, because probably so much time will have gone by that he will have forgotten much of what he learned the first time he made the repair.

This example illustrates the second way that the division of labor increases the efficiency of the learning process in connection with production: it increases the ratio of the time spent in using knowledge to the time spent in acquiring it. Our plumber spends a given amount of time learning how to make a given repair, and then makes that repair over and over again. The homeowner spends a given amount of time learning how to make a given repair, and then hardly ever uses the knowledge he has acquired. The learning time put in by the plumber is obviously much more fruitful. The same principle, of course, applies to all specialists in comparison with nonspecialists, and is the reason that it pays specialists to acquire vastly more knowledge about their work than it can ever pay nonspecialists to acquire.

Finally, the division of labor increases the efficiency of the learning process in connection with production by making education and communications—indeed, all the activities concerned with storing and transmitting knowledge—into specializations. These, like all other specializations, also tend to be carried on by those best suited for them. In this way, the diffusion of knowledge of all kinds, including, of course, all that pertains to production, tends to become more efficient.

Thus, the division of labor increases the degree to which knowledge of production is assimilated and therefore the proficiency with which it is used, the yield to the time spent in acquiring it, and the efficiency with which it is disseminated. These advantages, of course, are obviously closely related to the multiplication of knowledge that was discussed at the beginning of this investigation of the ways in which the division of labor raises the productivity of labor.

The division of labor also achieves a large increase in production simply by eliminating unnecessary motion in production. The tendency under the division of labor is to concentrate work of the same type in the same place, and, depending on the volume of work that can be so concentrated, to break it down into the simplest possible steps, consisting of the smallest possible number of separate motions.

For example, most factory-made products are produced under an arrangement whereby the typical worker remains in just one place and performs just one kind of operation in the course of his working day. Typically, he performs just one step in the making of just one component or part, or joins just one component or part to one other component or part. The advantages of such a system are that it eliminates the time that would otherwise be lost in walking back and forth from one place to another to do different kinds of work, in constantly picking up and putting down different types of tools, and in constantly having to finish up and perhaps clean up what one has been doing and warm up to what one is about to do.¹

Repetitious factory work is a further and important example of the division of labor's enhancement of the yield to learning. It represents the yield to learning being raised so high that people can live by virtue of knowing merely how to perform a few simple motions. Under the division of labor, the intelligence of businessmen, capitalists, industrial engineers, and managers, achieves the isolation, concentration, and coordination of small, distinct steps in production, which then constitute highly productive jobs for people even of very limited intelligence. Because of the productive efforts of the first group, highly sophisticated products, such as automobiles and even computers, can be produced by members of the second group—by people who otherwise could hardly even conceive of such products, let alone produce them.

The Use of Machinery

Finally, the division of labor raises the productivity of labor by constituting the foundation for the use of machinery in production. It does so, first of all, by creating a sufficient fund of knowledge in a society to make the production of machinery possible. As explained in the discussion of the multiplication of knowledge, the division of labor is indispensable to the production of all products requiring the existence of an extensive body of knowledge—a body of knowledge greater than can be held by any one individual or family, or even village or tribe. Virtually all machinery is in this category.

The division of labor is equally indispensable to the existence of machinery in providing the extensive and widely scattered range of materials necessary for the production and use of most machines, such as iron, copper, lead, tin, leather, rubber, timber, coal, oil, and so on. In the absence of division of labor among the different regions of the world, it would be virtually impossible to obtain the materials required for the production and use of machines.

In addition, also as explained earlier, the division of

labor makes science and invention into specializations carried on by geniuses, which, of course, greatly facilitates the invention of machinery. And, in reducing jobs wherever possible to a small number of distinct motions repeated over and over again, it enormously simplifies the problems of *designing* a machine or special tool to help do the work. As a result, machines and tools have frequently been invented by intelligent, ambitious workers who gave careful thought to the exact nature of the operations they performed every day and who thus discovered how their work might be aided by the application of some special mechanical device or implement.

Lastly, by concentrating a large volume of work of the same type in the same hands, the division of labor makes the use of machinery and specialized tools *economically worthwhile*. For example, it pays a plumber to acquire not only all kinds of knowledge about plumbing, but also all kinds of specialized plumbing tools that it would not pay a homeowner to acquire. In the same way, it pays a large-scale manufacturer to use all manner of machinery that it would not pay a small-scale manufacturer to use. This is because machinery and specialized tools are often very expensive. If their use is to be economical, they must be used fairly often, so that their high cost can be spread over a large number of units of output. Where this is not possible, it is probably cheaper to produce by hand. In concentrating work of the same type in the same place, the division of labor operates to ensure that the use of machinery pays. It increases the productive yield to specialized machinery just as it does to specialized knowledge, and thus makes its acquisition and employment worthwhile.

The above connections between the division of labor and the use of machinery make it possible to understand why the Industrial Revolution began in England in the late eighteenth century. At that time, England already possessed the highest degree of division of labor ever achieved and was also the world's greatest commercial nation. It thus possessed or had access to the necessary fund both of knowledge and of materials required for the construction of machines. By the same token, it also possessed conditions favoring the invention and design of machines and the conditions in which their use would pay.

Far more importantly, because the use of machinery is utterly dependent on the division of labor, it follows that the division of labor must indirectly be credited with all the magnificent advances in human life and well-being that have taken place over the last two centuries or more and that have been the result of the use of machinery. These advances, ranging from improvements in sanitation to high-speed travel by jet aircraft, and elo-

quently summarized by the radical lengthening of life expectancy, were described at length in the preceding chapter.²

2. The Division of Labor and Society

All of the preceding discussion of the division of labor can be summarized by saying that the division of labor increases the efficiency with which man is able to apply his mind, his body, and his nature-given environment to production. It expands his capacity to store and use knowledge, which knowledge it raises to a standard set by the most intelligent members of society. This standard in turn tends to rise higher and higher in each succeeding generation, as creative geniuses again and again enlarge the stock of technological knowledge. The division of labor also increases the degree to which knowledge of production is assimilated, the yield to the time spent in acquiring it, and the efficiency with which it is disseminated.

It increases the efficiency with which man applies his body to production inasmuch as it enables everyone to concentrate on whatever he is relatively best suited for by virtue of his bodily endowment. It also eliminates unnecessary motion in production. And, finally, it makes possible the addition of machine and mechanical power to the power of human muscles. This last enables man to accomplish physical results that would otherwise be unthinkable.

Similarly, by means of geographical specialization the division of labor increases the efficiency with which man applies his nature-given environment to production. And it does so even more by the use of ever improved machinery and methods of production that flow from the heightened and progressively increasing efficiency that it lends to man's use of his mind and body. This enables man to obtain progressively more from his environment.

On the basis of all of the foregoing considerations, it should be obvious that from the perspective of the production of wealth and all that depends on the production of wealth, a division-of-labor society is the form of society that is appropriate to man's nature. While man always possesses the faculty of reason, a division-of-labor society is necessary if he is to use his rationality efficiently in production. It is necessary if he is to actualize the productive potential provided by his possession of reason.

It should be equally obvious that the existence of a division-of-labor society is to the material self-interest of every individual. Whoever, in the words of von Mises, prefers wealth to poverty and life and health to sickness and death, is logically obliged to value the existence of a division-of-labor society and all that it depends on. For

it is the essential foundation of all significant wealth and of the vital contribution made by wealth to man's life and health. Take away a division-of-labor society, and production shrivels to the level of medieval feudalism, with its consequently recurring famines and plagues and resulting average life expectancy of twenty-five years—years, it should never be forgotten, whose passage was marked with cold, hunger, exhaustion, and pain. Apart from the amelioration provided by Western aid in the form of food and medicines, such continues to be the miserable condition of human life today in all that vast part of the world that is not integrated into the division of labor.

Thus, the widely held notion that life in society requires the sacrifice of the individual's self-interest is totally mistaken in regard to a division-of-labor society. That notion applies only to societies characterized by force and plunder, not to a division-of-labor society. A division-of-labor society represents the mutual cooperation of individuals for the purpose of achieving their own individual ends. The radical and progressive increase in the productivity of labor it brings about makes it possible for everyone to achieve his ends incalculably better within its framework than outside of it.³

These considerations have major implications for ethics. They imply that the ethical principle of respect for the persons and property of others is not something that is arbitrarily enjoined upon the human race by an outside authority, but has a rational basis in the requirements of the individual serving his own material self-interest. In order for the individual to enjoy the benefits of the division of labor, he needs the existence of other people who participate in the division of labor with him. He also needs those others to be secure in their persons and property—that is, to be free from the initiation of force and the threat of the initiation of force—and thus to be motivated and able to work and produce as efficiently as possible, so that there will be the most abundant and best possible supply of goods available for him to buy. Thus, it is to his self-interest that others, as well as himself, be secure from such threats as murder, assault, and robbery, and that others, as well as himself, be free.⁴ These principles apply to *all* other human beings the world over who might potentially associate with him in the division of labor and thus contribute to his material well-being by enlarging and improving the supply of goods available for him to buy. Thus, the gains from the division of labor constitute an objective foundation for the existence of good will on the part of each individual toward the rest of mankind.

Furthermore, it can be stated categorically that these principles are in no way lessened, let alone contradicted, by the existence of free economic competition. On the

contrary, as later chapters will demonstrate, they are powerfully reinforced by the existence of such competition. The effect of free economic competition is to improve the organization and efficiency of the division of labor. It is both to provide everyone with the opportunity to work and produce in the area in which he is best suited and to increase the output per unit of labor, especially on the part of individuals of lesser ability. Thus it enables everyone to enjoy a higher and continually rising standard of living.⁵

3. Rebuttal of the Critique of the Division of Labor

Because of the dependency of human life and well-being on wealth, and of wealth on the division of labor, it should now be obvious that in the name of the value of human life and well-being, a division-of-labor society is itself a cardinal value, and should be upheld with all the means at our disposal. Indeed, every individual who decides that he is better off working for money and buying the things he wants, rather than attempting to produce for himself, acts to build or maintain the division-of-labor society as he thereby positions himself in it; and in this way he affirms its value. A division-of-labor society is formed and maintained precisely on the basis of such self-interested actions of individuals.⁶

Despite the fact that man's vital interests depend on it, the division of labor has been attacked, most notably by Marx and Engels, who blame it for making work boring and unpleasant, for "alienating" the worker from his work, and for making him narrow and one-sided rather than broad and well rounded in his interests and capacities. Socialism, they boast, will abolish the division of labor and turn work into a pleasure.⁷

These accusations are nonsensical. Work in a routine factory job may well be boring and unpleasant for many people. This is particularly likely to be so in the case of people who have the potential for doing much more intellectually demanding work but who, for psychological reasons, are unwilling to challenge themselves and acquire the necessary skills. Yet even so, routine factory work is far less boring and unpleasant than the work of primitive farmers, which preceded it, and from which tens of millions of people in the Western world willingly fled to take factory jobs. Even now, large numbers of housewives consider it less boring than housework, which consists of little more than a wide variety of boring jobs. A dull job performed for money is almost always less dull than one performed merely for the sake of a given physical result, because the money can be exchanged for so many different things and thus at least ties the work to interesting possibilities.

Furthermore, if a fuller measure of capitalism existed,

even the otherwise most monotonous, repetitious types of factory work would be given an important measure of challenge and excitement through the establishment of piecework and competition among individual workers and, perhaps, among assembly-line teams. Under such conditions work becomes perceived as the direct, immediate means of putting money into one's pocket. Workers then go at the otherwise duller kinds of jobs with enthusiasm. Physically, the duller kind of job can be no duller than pulling the handle of a slot machine over and over again, which multitudes eagerly do in gambling casinos, in the hope of winning a jackpot. In a factory operating under the piecework system, each such operation brings a guaranteed small jackpot, as it were.⁸

It is also significant that a free market operates to offer premium wage rates for any jobs that most people find relatively dull and unappealing, and, by the same token, to reduce the wage rates of jobs that most people find relatively exciting and attractive.⁹ Consistent with this fact, to the extent that intellectually overqualified people presently in relatively dull jobs decided to do what was necessary to find more demanding, more interesting, and, at the same time, higher-paying jobs—higher paying because of the higher skill requirements—the effect would be that everyone who had to remain in the relatively dull jobs would be compensated by receiving higher wages. The effect of the establishment of the higher wages in turn would be to provide an inducement to employers to seek ways to make such jobs more interesting, in order to attract workers without having to offer such higher wages. (Of course, the increase in the supply of labor in the more-skilled fields, into which the previously overqualified workers moved, would operate to reduce wage rates in those fields.)¹⁰

The charge that factory work is "alienating" rests on a view of the average factory worker as being incapable of intellectually understanding the importance of his particular work to the final product. It assumes that to take personal pride in his work, a worker has to be in the position of a medieval cobbler and oversee the process from raw material to finished product. It does not see that a worker can conceptually understand that, for example, the welds he performs help to keep an airplane in flight or an automobile in operation. The charge of alienation does not see that in a division-of-labor society a worker can take pride in the fact that he contributes to the production of magnificent products whose very existence would appear absolutely miraculous to any medieval cobbler.

Finally, it is in a division-of-labor society that the average worker, for the first time in all of human history, has the opportunity of actually becoming something of a Renaissance man, if that is what he chooses to be. The

division of labor has raised the productivity of labor so high that today the average member of a division-of-labor society has both substantial real wealth at his disposal and substantial leisure in which to enjoy it. The average worker today can easily afford an extensive personal library—in paperback—of books on science and philosophy. He can afford an extensive collection of fine musical recordings and prints of the greatest works of art. He has the leisure to engage in all kinds of athletic activities, including year-round swimming if he lives in a sizable town or city. In short, he has open to him in no small measure precisely the kind of life that the ancient Greeks thought could be enjoyed only by a slave-owning aristocracy. Further improvements in the productivity of labor under the division of labor will place still more wealth and leisure at the average worker's disposal.

In addition, the proportion of truly interesting and challenging jobs in the economic system has steadily increased with the progress of the division of labor, and will continue to increase in the future, if the division of labor and capitalism are preserved. Today, a far larger proportion of the population than ever before works in the professions, in management, and in various mechanical and skilled trades that have sprung up and grown with the intensification of the division of labor. These jobs are in addition to those of the custom craftsmen that came into existence with the first revival of the division of labor in early modern times, and that the enemies of the division of labor like to contrast with factory work—forgetting that before the factories, very few people held such jobs as craftsmen and that the overwhelming majority were half-starving, illiterate peasants. Computerization and automation, if allowed to proceed, will make possible substantial further improvements along these lines.

Furthermore, Marx and Engels were wrong because the wealth and leisure and the resulting education and level of knowledge that a division-of-labor society makes possible are powerful forces working *against* feelings of “alienation.” While it is true that alienation—a sense of lack of belonging and lack of control in one's life—is a growing problem in present-day society, it is not because of, but *in spite of* the existence of the division of labor. The wealth the division of labor makes possible enables us to gain control over our physical circumstances. Our houses are not blown down by every strong wind. We do not starve when the rain does not fall or when the locusts come. We do not, as a common occurrence, see our children and loved ones or our friends and neighbors dead and dying around us. We do not live in the constant fear of disaster, disease, and death. Yet that is the normal state of life in non-division-of-labor societies. By the same token, when a disaster does strike us from which

we cannot escape, we are at least able to understand it as a natural phenomenon, and not as the visitation of the wrath of some mysterious power. Wealth and education are the physical and intellectual means of being in control of our lives, and therefore of not being alienated. Both depend on the productivity of a division-of-labor society.

Marx and Engels were correct about one thing, however: socialism, if it were ever imposed on a global basis, would abolish the division of labor. The division of labor that socialist regimes inherit from a preceding era of capitalism can endure, in a crippled, highly inefficient state, only so long as an outside capitalist world exists which is large enough, and foolish enough, to subsidize the socialist regimes with such things as free food and the proceeds of government-guaranteed loans, and which provides a continuous market for the purchase of emergency supplies.¹¹ Recent revelations about the poverty of Eastern Europe and the former Soviet Union fully confirm these propositions.

A division-of-labor society is a *capitalist* society.

4. Universal Aspects of Production

While the division of labor is the hub of production under capitalism, and creates the need for the science of economics, there are other important aspects of production as well. These aspects are present in one form or another both under capitalism and all other imaginable forms of economic activity, such as feudalism and that of Robinson Crusoe on a desert island. They may be described as universal aspects of production. It behooves economics as a science to take notice of them. Thus we shall consider here the general concepts of production, product, producer, labor, land, and capital goods, and also the concept of consumption with respect to its multifaceted relationship to production. Later on, in Chapter 11, we will show how the existence of the division of labor profoundly modifies the whole concept of productive activity, including these other aspects.¹²

Physically, production can be defined as man's alteration of matter in form or location, in accordance with conscious design, in order to make the matter thus altered serve a further purpose. (In a division-of-labor society, as we shall see, the concept of production becomes more complex. It incorporates, as a necessary feature, the earning of money, and comes to include the rendition of services performed for money.¹³) When the matter thus altered undergoes some significant physical, chemical, or biological change—such as the making of flour from wheat, metal from ore, or wine from grape juice—man may be said to produce a distinct product, and a new good may be said to result. Where the alteration is relatively minor, or consists of a mere change in location—for

example, removing stains from clothing or carrying water from one place to another—production takes place, but a distinct product does not result; no new good is produced. A product is matter that has been altered in one or more of the above ways (e.g., flour), or the *alteration* in matter that we perceive as essentially unchanged (e.g., the removal of a stain). A producer in the physical sense is one who effects such alterations.

All production, of course, entails the performance of human labor. Labor is the means by which man's mind transmits his designs and purposes to matter. It is man's application of his bodily and mental faculties for the purpose of altering matter and thereby making it serve a further end.

By the same token, all production also entails the presence of preexisting matter, which is to be altered. The ultimate source of this matter is always nature. The name which economists have traditionally given to nature's contribution to production is land. "Land" includes land as we normally think of it, namely, pieces of ground, *plus* all the natural resources within it and all the trees and plants and animals that are naturally present upon it—i.e., present without man's intervention. It also embraces bodies of water and their contents, air, and, eventually no doubt, even outer space, insofar as these things are employed in production. Land and labor together are sometimes referred to as the original factors of production. (The description of land as an original factor of production can be misleading, however, insofar as man is responsible for whatever wealth-character it possesses.¹⁴)

Materials of production which are themselves products or otherwise the result of the previous performance of labor, plus tools, implements, and machines, and buildings used in production (and land too, insofar as it has been improved by the previous performance of labor), have traditionally been called capital goods. It must be stressed, however, that this description can at most be allowed to stand only in the context of a non-division-of-labor economy. As will be shown later, the division of labor exerts such a profound influence on virtually every aspect of economic activity that its existence requires that many materials of production, and even many tools and machines be categorized as consumers' goods rather than capital goods—for example, the materials required for serving meals in the home, and all sorts of tools and machines found in homes, such as knives and forks, hammers and screwdrivers, washing machines, sewing machines, and automobiles. In a division-of-labor society, the concepts of capital and capital goods, like that of production, come to incorporate as a necessary feature the purpose of earning a money revenue or income.¹⁵

Products produced are continuously used up, worn out, or simply deteriorate through the action of nature, as

when they rust or rot. The using up, wearing out, or deterioration both of products and nature-given goods (such as mineral deposits) is *consumption*, in its physical sense. And a consumer in this sense is one who uses goods up, wears them out, or in whose possession they deteriorate.

Production and consumption are related in a double way. On the one hand, every product produced is subsequently consumed. On the other hand, every product reflects *a prior consumption in the process of its own production*. The production of bread, for example, entails the consumption of flour and other ingredients, and of the pots, pans, oven, and building which are employed in its production. There is no product the production of which does not entail consumption. Even the cave man, in producing the very first products, had to consume nature-given goods. And all production above the cave man level entails a consumption of previously produced *products*. The materials consumed in production come, for the most part, to be themselves products, and even where the materials remain nature-given goods, as in mining, products are nonetheless consumed in the form of the wearing out of tools, implements, machinery, buildings, and other installations, at least some varieties of which are employed in all branches of production without exception once economic activity advances beyond the most primitive level.

The recognition that consumption is entailed in the very process of production itself, led the classical economists to distinguish between two, and sometimes three, very different kinds of physical consumption, which they called, respectively, productive, unproductive, and re-productive consumption. Retaining these terms, I define them as follows:

Productive consumption: consumption for the purpose of production. For example, the consumption of flour and ovens for the purpose of baking bread, as above; the consumption of steel and stamping equipment for the purpose of producing automobiles; the consumption of cloth and sewing machines for the purpose of making clothing.

Unproductive consumption: consumption *not* for the purpose of production. For example, the eating of bread, the driving of an automobile for pleasure, the wearing of clothes.

Reproductive consumption: that variety of productive consumption in which the product produced can play the same role in further production as the goods consumed in its own production, or can be employed in the production of such products. The consumption of seed in the production of wheat and the wearing out of trucks in making deliveries to truck factories are obvious examples of reproductive consumption. The same phenome-

non is no less present, however, in the wearing out of oxcarts in the construction of a railroad. For though physically very different, oxcarts and railroads play the same role in production, in that both are means of transport. The using up of steel in the manufacture of iron mining equipment is likewise reproductive consumption, as is the subsequent wearing out of the iron mining equipment. For iron mining equipment indirectly serves in the production of steel, which, in turn, serves in the production of iron mining equipment.

The concepts of productive and, especially, reproductive consumption are closely related to a proper concept of capital goods. Capital goods, in the physical sense, are goods productively or reproductively physically consumed. For example, the flour and ovens, steel and stamping equipment, cloth and sewing machines, and the seed, trucks, oxcarts, and steel and iron mining equipment, as above. As we shall see, in the context of a division-of-labor, monetary economy, in which anything that is used in the production of a product to be sold can make possible its own replacement by way of exchange—that is, by using the sales proceeds its products bring in, to purchase its replacement—the concepts productive consumption and reproductive consumption become synonymous.¹⁶ And the concepts capital goods and capital come to be inseparably connected with the question of whether or not the goods are purchased, or the sums of money are expended, for the purpose of bringing in subsequent sales revenues.¹⁷

The aggregate of capital goods in the possession of an individual can be described as his *capital*. And capital can be defined as *wealth reproductively employed*—that is, as wealth employed in the production of wealth. (In the context of a division-of-labor economy, capital is wealth employed in the earning of money.)

It is obvious that if the supply of capital goods is to be maintained, a substantial proportion of production must be devoted to their production in order to replace the supplies undergoing productive consumption. If the proportion of labor and capital goods devoted to the production of capital goods is large enough to more than offset productive consumption, then capital accumulation takes place—i.e., the supply of capital goods grows. If the proportion is insufficient, then capital decumulation takes place.¹⁸

The supply of capital goods is of vital significance to production because it is a major determinant of the productivity of labor—i.e., the output per unit of labor. A larger supply of capital goods per capita operates to raise the productivity of labor, and a smaller supply to reduce it. More capital goods make it possible to produce not only more of various products, but products whose production would otherwise be completely impossible.

For example, while a plow enables a farmer to grow more food than he could grow without it, a blast furnace of some sort is necessary in order to produce any steel at all. A growing supply of capital goods is indispensable to the adoption of more advanced technologies and to the continuing rise in the productivity of labor.¹⁹

As previously indicated, the existence of division of labor operates to raise the productivity of labor in large measure by virtue of increasing the supply of capital goods per capita.²⁰ This is actually the effect of division of labor in all the ways that it serves to increase production, insofar as the products are capital goods. In particular the most important sources of gain from the division of labor—namely, the multiplication of knowledge, the benefit from the existence of geniuses, and geographical specialization, all of which are indispensable to technological progress and the use of machinery and ever-improved machinery—make their contribution to the productivity of labor mainly by means of bringing about capital accumulation.²¹

The present discussion of the role of division of labor in capital accumulation indicates that in addition to the proportion of total production in which capital goods are produced being a determinant of their supply, and thus of the productivity of labor, there is a further, equally important factor: namely, the general efficiency with which labor and existing capital goods are used. The more efficient an economic system is in the utilization of its labor and existing supply of capital goods, the greater will be its ability to accumulate additional capital goods. This is because a greater efficiency in the utilization of labor and existing capital goods means that with any given supply of capital goods it can produce a larger total product, including a larger supply of capital goods for any given proportion of its productive efforts that it devotes to the production of capital goods. The effect of this, in turn, is that the proportion of its output which it needs to have in the form of capital goods in order to make possible the replacement of the capital goods consumed in production—its maintenance proportion, so to speak—is correspondingly reduced. To whatever extent the economic system was already devoting to the production of capital goods a larger proportion of its efforts than was required for mere replacement, this reduction in the maintenance proportion further widens the margin by which it accumulates capital.

This point can be illustrated by considering the conditions of a self-sufficient farmer, whose own product is the source of the capital goods he uses in further production. If such a farmer can use one bushel of crop in the form of seed to produce an output of two bushels of crop, then in order to maintain his stock of seed and produce the same-sized crop in the next year, the farmer must

employ half of his output as seed. If he becomes more efficient, and can produce three bushels of crop for every one of seed, then he requires only one-third of his output to replace his stock of seed. If he continues to devote half or more of his output to seed, he is now enabled to accumulate capital and increase his production, or to do so more rapidly than before.

The exact same principle applies to the accumulation of capital goods in a complex division-of-labor economy such as our own. Just as in the case of the self-sufficient farmer, the physical source of capital goods for us is the product of our economic system. For taking a division-of-labor economy as a whole, it resembles the situation of the self-sufficient farmer in that there is nothing outside of it to provide capital goods. The physical source of capital goods in a division-of-labor economy, as with a self-sufficient farmer, is always its own output.

It is worth noting that production with capital goods always represents an indirect, more time-consuming process of production as compared to production without capital goods. For labor must first be applied to the production of the capital goods and only then to the production of consumers' goods. The greater lapse of time between the performance of labor and the achievement of its ultimate result is, of course, compensated for by the larger size of the result and by the fact that in many cases results of the same kind could simply not be ob-

tained otherwise. The use of labor in a hand-to-mouth process of production—for example, to pick fruits and nuts growing wild in the forest—is the most direct, least-time-consuming method of production one might imagine. Yet the product of such a process of production is insignificant in comparison with processes of production in which labor is used first to produce tools and implements; and if labor were not first used to produce materials as well, no products could be produced beyond the crudest, most primitive type.²² The division of labor is intimately bound up with the question of the time factor involved in production insofar as one group of workers begins its production with capital goods produced by previous groups of workers. Such temporal succession in the stages of division of labor can be described as the division of labor in its vertical aspect.

In any discussion of universal aspects of production, some mention must be made of the law of diminishing returns, which has application under all economic conditions. However, inasmuch as this law has already been explained in the last chapter, it is not necessary to explain it again.²³ It is only necessary to stress that it is the framework provided by the division of labor and capitalism, and the resulting continuous ability to achieve technological progress and accumulate capital, that makes it possible to counteract and more than counteract the influence of the law of diminishing returns.

Notes

1. These particular advantages of the division of labor are sometimes lost sight of in misguided efforts to make unskilled factory jobs more interesting. One such recent effort in the automobile industry failed with a loss of over \$800 million in just eighteen months. This was a case in Sweden, in which assembly lines were abolished and replaced by work groups of ten to fifteen members with responsibility for building vehicles on their own. See "Saab Is Closing Plant After Venture's Loss," *New York Times*, February 9, 1991.

8. The piecework system is often mistakenly attacked on the grounds that it operates perversely. To wit: it is argued that the incentives the piecework system provides result in increased production, which, if great enough relative to the demand for the product, in turn results in the piece rates being cut and thus in workers earning less money than they did before. The error in this argument is essentially the same as that which is present in the doctrine of overproduction and in criticisms of Say's Law. See below, pp. 561–564, in particular the analysis of the hypothetical case of the potato growers who double their production and earn less as the result of doing so. See also p. 568 and pp. 655–656. The ultimate effect in all such cases is to raise the general standard of living, including the standard of living of those who might initially lose by the process of improvement.

9. For the explanation of this fact, see below, p. 195.

10. For a discussion showing how the consistent implementation of procapitalist policies, namely, a free market in labor and a 100-percent-reserve gold standard, would create a wide range of readily available employment opportunities, see below, p. 594. In such conditions, people would have an incentive to develop the ability to do a variety of jobs and to move between those jobs.

CHAPTER 5

THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM I

PART A

THE NATURE OF THE DEPENDENCIES

Chapter 4 explained how the division of labor is essential to the existence of a high and rising productivity of labor. This and the next three chapters demonstrate the dependence of the division of labor on the fundamental economic institutions of a capitalist society. These institutions, of course, are private ownership of the means of production, saving and capital accumulation, exchange and money, economic competition, economic inequality, and the profit motive and the price system. By the end of Chapter 8, the dependence of the division of labor on the institutions of capitalism will have been established so thoroughly that the proposition will appear unexceptionable that in the long run the division of labor itself is an institution of capitalism.

1. Dependence of the Division of Labor on Private Ownership of the Means of Production

Private ownership of the means of production is the most fundamental of the institutions of capitalism, along with freedom and the pursuit of material self-interest. It underlies a division-of-labor society in a direct way and in a variety of indirect ways.

The direct dependence of the division of labor on

private ownership of the means of production is based on the very nature of the gains provided by the division of labor. These gains, above all the multiplication of knowledge and the benefit from the existence of geniuses, fundamentally derive from the fact that individuals possess separate, independent minds, which permit, indeed, require them to have separate independent knowledge and to make separate, independent judgments and decisions. In a division-of-labor society, each person benefits from the fact that other people possess knowledge which he does not, and an intelligence separate from and often greater than his own. His benefit requires that others be able to acquire and apply their knowledge on their own initiative, without having to await his orders, approval, or permission, which, in the nature of the case, he would be unable to give in any rational way, since he necessarily lacks the knowledge that would be required to do so.

Now, in order for people to act and produce on any significant scale, they must possess material means of action and production: they must possess wealth. In order for them to act and produce separately and independently from one another, *they must hold wealth separately and independently from one another*—that is, there must be private property, including private ownership of the means of production.¹

In essence, private property and private ownership of the means of production are fundamental and essential to a division-of-labor society because the separate, independent thinking and acting of individuals is fundamental and essential to it, and because they are the material

requirement of such separate, independent thinking and acting.²

Socialism and Collectivism Versus Economic Planning

Just as capitalism—private ownership of the means of production—is indispensable to the existence of a division-of-labor society, so, by the same token, socialism and collectivism are incompatible with the existence of a division-of-labor society.³ The truth of these propositions is confirmed by the collapse of socialism in Eastern Europe and—how wonderful the words sound—the *former* Soviet Union. Despite extensive Western aid, economic conditions in the Communist bloc were so bad for so long that finally all hope of improvement under socialism has been abandoned and attempts are now underway to institute private ownership of the means of production and establish a price system.

The incompatibility of socialism and collectivism with a division-of-labor society would long since have been blatant if the capitalist countries had not continuously rescued the Soviet Union and its allies from famine, with massive supplies of grain sent for free or on government-guaranteed credit that was never intended to be repaid. Even the grain *purchases* made by the Soviet Union and its allies ultimately depended on the aid of Western governments, which guaranteed investments made in the development of natural resources and in the construction of factories in the Soviet Union and other Communist-bloc countries. These investments, particularly those in the development of natural resources, in which the quality of the product does not enter as a decisive factor, were the foundation of most of the exports of the Soviet Union and the Communist bloc and thus of their ability to obtain funds with which to make purchases from abroad. In the absence of such Western aid, a series of famines—the necessary consequence of the massive inefficiencies of socialism—would have led to a flight from the cities and resettlement of practically the whole of the surviving population of the Communist countries on farms, in an effort of people to secure a food supply. This would have meant the end of all significant division of labor in those countries and their reversion to the economic conditions of feudalism.

It should be realized that collectivism openly demands that everyone think and act as a unit. It leaves no room for the vast differentiation and individuation of knowledge on which a division-of-labor society rests. The propaganda of socialism fully displays this absurdity when it pretends that under socialism all economic decisions will be arrived at democratically. In order for people intelligently to vote on all economic decisions, everyone would have to have all the necessary knowl-

edge pertaining to all economic decisions, which is clearly impossible in a division-of-labor society. It would mean, for example, that the voters would have to decide such questions as whether a new steel mill should be built in Gary, Indiana, or somewhere else, what kind of steel mill it should be, how large it should be, and so on. In the face of hundreds or thousands of such questions arising every day, the voters would have to devote their lives to nothing else, and still they would be almost entirely ignorant about the matters raised in each case.

Socialism is not rescued from its incompatibility with a division-of-labor society by substituting the dictatorship of an alleged expert or body of experts for the democracy of the ignorant masses. For now, instead of demanding that everyone know everything about production, it demands that one person or several people—the Supreme Dictator or the members of the Central Planning Board—know everything about production. The very expression “central planning” describes the essence of this absurdity. It means that one consciousness must be able to see and plan the entire economic system, either alone or in consultation with one or more other such all-seeing consciousnesses. For central planning means the planning of the entire economic system as an indivisible whole.

Socialism is incompatible with a division-of-labor society because in all of its versions it is incompatible with a division of *the intellectual labor* required in the planning of the conduct of the economic system. When it attempts such an intellectual division of labor, as it necessarily must, the result is contradictory partial planning. This is a state of affairs in which separate ministries, industries, regions, and even individual factories and farms plan in discoordination and at cross purposes. In a word, it is economic chaos.⁴ As a result of this chaos, the whole division of labor disintegrates—or would in the absence of aid from capitalist countries. For people are subjected to a chronic inability to obtain vital supplies from others and thus must attempt to produce them themselves.

The lack of vital supplies includes all manner of things. There are not only shortages of food, but also shortages of such things as lubricants, electric power, and raw materials and component parts of all kinds, and, of course, labor and all kinds of consumers' goods.⁵ It is in response to such conditions that Soviet factories found it necessary to attempt to manufacture even their own screws and nails. Thus, for example, without any awareness of the fact that the conditions he described were hostile to the division of labor, an admirer of the Soviet system wrote:

There is considerable evidence that Russian plants do for themselves many things—like producing screws with

slow-speed machinery—which could be better done by others—in this case, specialized screw manufacturers using high speed equipment. But this desire to be independent of others, in part at least, grows out of the Soviet effort to operate its plant capacity at a pace rarely achieved under capitalism except in wartime. In fact, the sort of barter deals just discussed are not too different from those which take place in a capitalist economy under the impact of *wartime shortages*.⁶

In describing such conditions, another observer wrote:

For a Soviet factory—or a Soviet research institute—the best response to unreliable business partners is self-sufficiency. When the planners decided to build the giant Fiat factory, they decided to make it almost entirely self-sufficient. Except for electrical equipment, window glass and tires, every part used in Zhiguli—every nut, bolt, seat cover and piston ring—is made in the factory itself. Gersh Budker’s Institute of Nuclear Physics in Novosibirsk couldn’t buy the instruments it needed, so the scientists there began to make their own. This kind of self-reliance is expensive and inefficient. Yet no amount of planning can provide the trust and reliability that could substitute for it.⁷

The fact is that such results are inescapable under so-called central planning. They can be avoided only by means of capitalism and its price system.

Happily, at long last, it appears that after more than seventy years of abject failure, the concept of central planning is now being abandoned in the former Soviet Union. The process of abandonment of the concept appears to be well underway even in Communist China. Hopefully, within the next few years, these and all other socialist countries will have made the transition to private ownership of the means of production and capitalism.

Capitalist Planning and the Price System

Division of labor in the planning process is possible only under capitalism. This is because of the existence of the price system, which is unique to capitalism. Under capitalism each individual plans his own particular sphere of economic activity. But he plans on the basis of a consideration of prices—the prices he will receive as a seller and must pay as a buyer.

The consideration of prices is what integrates and harmonizes the plans of each individual with the plans of all other individuals and produces a fully and rationally planned economic system under capitalism. For example, a student changes his career plan from actor to accountant when he contemplates the vast difference in income he can expect to earn. A prospective home buyer changes his plan concerning which neighborhood to live in when he compares house prices in the different neighborhoods. And businesses change their plans concerning product lines, methods and locations of production, and every other aspect of their activities, in response to

profit-and-loss calculations.

All of these changes represent the adjustment of the plans of particular individuals and businesses to the plans of others in the economic system. For it is the plans of others to purchase accounting services rather than acting services that cause the higher income our student can expect to earn as an accountant rather than as an actor. It is the plans of others willing and able to pay more to live in certain neighborhoods, and less to live in certain others, that determine the relative house prices confronting our home buyer. It is the plans of its prospective customers, of all competing sellers of its goods, and of all other buyers of the means of production it uses or otherwise depends on, that enter into the formation of the prices determining the revenues and costs of any business firm and thus what it finds profitable or unprofitable to produce.

Now the fact that capitalism even *has* economic planning, let alone the only possible kind of rational economic planning, is almost completely unknown. Practically everyone under capitalism has been in the position of Molière’s M. Jourdan, who spoke prose all his life without ever knowing it. The overwhelming majority of people have not realized that all the thinking and planning about their economic activities that they perform in their capacity as individuals actually *is* economic planning.⁸ By the same token, the term “planning” has been reserved for the feeble efforts of a comparative handful of government officials, who, having prohibited the planning of everyone else, presume to substitute their knowledge and intelligence for the knowledge and intelligence of tens of millions, and to call *that* planning. This is an incredible state of affairs, one which implies the most enormous ignorance on the part of the great majority of today’s intellectuals, from journalists to professors.

The dependence of the division of labor on the price system points the way to its *indirect* dependence on the institution of private ownership of the means of production. The price system rests on the profit motive and the freedom of competition. Operating in conjunction with one another, these are the elements that drive and regulate the price system—that determine the formation of all individual prices and their integration into a system. The profit motive and the freedom of competition, in turn, vitally depend on the institution of private ownership of the means of production.

It is necessary to explain here the nature of both of these sets of dependencies: that of the price system on the profit motive and the freedom of competition and, in turn, that of the profit motive and the freedom of competition on private ownership of the means of production.

The profit motive—financial self-interest—makes every-

one be concerned with the revenue or income he earns and the costs or expenses he incurs. As stated, precisely this is what harmonizes and integrates the economic plans and the economic activities of all the separate businesses and individuals who make up a division-of-labor society. While the principles describing just how this occurs are the subject matter of price theory and are explained at length in the next three chapters of this book, this much can be stated now, as a brief, advance indication: Namely, the profit motive provides powerful incentives for the steady expansion and improvement of production and, at the same time, operates to keep the relative size of all the various industries and occupations in proper balance. It makes production accord with the will of the ultimate buyers—the consumers—and ensures that the production of each individual good takes place in a way that is maximally conducive to production in the rest of the economic system. The profit motive is what balances the demand and supply of each product and ensures the most rational and efficient distribution of each product over space and time—among all the markets that compete for it—and its delivery into the hands of those individuals who, within the limits of their wealth and income, need or desire it the most. The profit motive ensures the most rational and efficient allocation of capital and of every type of labor and material among its possible alternative uses, and makes the economic system respond to changes in economic conditions in the most rational and efficient manner possible.

Thus, the profit motive is what prevents any sort of “anarchy of production” and, instead, creates economic order and harmony out of the activities of all the different individuals who comprise the economic system. It is what enables capitalism to be an economic system that is rationally and cohesively planned by each and every individual who participates in it.

If the profit motive is the engine which drives the price system, competition and the freedom of competition are the built-in regulator which provide the essential context in which that engine operates. What this means is that in seeking to serve his financial self-interest, every seller under capitalism must be aware that there are other sellers or potential sellers who might sell to his customers and thus that he must accordingly limit the prices he asks. By the same token, every buyer under capitalism must be aware that there are other buyers or potential buyers who might buy from his suppliers and thus that he must set the prices he offers accordingly.

Now while the profit motive and the freedom of competition are the elements that drive and regulate the price system, as stated, they themselves in turn rest on the foundation of private ownership of the means of production.

Private ownership of the means of production is what makes the profit motive operative in the formation of prices, the prices both of means of production and of products. Furthermore, private ownership of the means of production underlies the very existence of the incentives of profit and loss, in that it is private property, above all in the form of private ownership of the means of production, that is the substance of what is gained or lost by producers. Without the ability to accumulate holdings of private property, there would be nothing for producers to gain except the ability to enlarge their immediate consumption, and nothing at all for them to lose, because losses can be losses only of preexisting property. With private ownership of the means of production there is not only the incentive of profit and loss to use the means of production profitably but also the vitally important fact that an individual’s control over the means of production is increased or decreased to the extent that he uses them profitably or unprofitably.

This last results from the fact that those owners who use the means of production profitably are in a position to save and reinvest, in proportion to the extent of their profits. To the extent that their sales proceeds exceed their costs, they obtain the funds not only to replace the means of production with which they began but to more than replace. They are thus enabled to enlarge their control over the means of production. By the same token, those owners of the means of production who suffer losses correspondingly lose control over the means of production. Their losses mean that their sales proceeds are less than their initial outlays and thus that they lack the funds to replace the means of production with which they began.

Thus private ownership of the means of production is what gives the profit motive virtually all of its economic influence: it enables the profit motive both to be operative in the formation of the prices of means of production and products and to direct the use of the means of production. At the same time, it enables success or failure in earning profits to determine the extent of one’s control over means of production in the future. And, of course, it is what gives the profit motive its strength.

As to economic competition: private ownership of the means of production underlies economic competition, in that economic competition presupposes separate, independent producers, who, in order to be separate and independent, must hold the wealth they use in production separately and independently from one another. Thus competition among producers presupposes private ownership of the means of production. Furthermore, the freedom of competition, like virtually all other freedoms, is an aspect of property rights: it is the freedom of owners of means of production to employ their means of produc-

tion in any branch of industry they choose.⁹

In addition to its dependence on the profit motive and freedom of competition, the price system, of course, also depends on the institutions of exchange and money. Prices are sums of money exchanged for units of goods or services. The very phenomenon of exchange presupposes the separate ownership of the things exchanged. Exchange is a mutual transfer of property between two parties, with the property of each being given as the condition of receiving the property of the other. A collectivist monopoly on production, which is the essence of socialism, is incompatible with the means of production being exchanged or, therefore, having prices. Capital goods cannot be bought or sold because all capital goods are owned by the same party: the state. At the same time, the leading purpose of socialism is supposed to be the removal of labor from the status of a commodity that is bought and sold in the market; and, indeed, labor cannot be bought and sold under socialism except on the terms arbitrarily dictated by a universal monopoly employer: the state. Thus, private ownership of the means of production is essential for the existence of markets and of market prices of the means of production.¹⁰ It is essential both for the very existence of a market in capital goods and thus for prices of capital goods, and for the existence of employer competition in the market for labor and thus for wage rates greater than the barest minimum of subsistence.

Closely related to the above, the price system further depends on the institution of saving and capital accumulation, in that the prices of the means of production are not paid by the consumers, who purchase only the ultimate final products, but by businessmen. All the materials and supplies, all the tools, equipment, and labor services used in production are purchased and paid for by businessmen, almost entirely out of accumulated capital, not by the ultimate consumers out of consumption spending.¹¹ The prices of all the means of production, therefore, depend on saving and capital accumulation. And, as indicated previously, saving and capital accumulation vitally depend on the institution of private ownership of the means of production and its security. In order for people to save and accumulate capital, to improve the productive property at their disposal in any way, or even just to maintain it, they must have the expectation of benefitting from such action. They can rationally have that expectation only if that wealth—those means of production—are securely their private property.

Thus, through each of these four roots—the profit motive, competition, exchange and money, and saving and capital accumulation—the price system is grounded in the institution of private ownership of the means of production.

Further dependencies of a division-of-labor society on the institutions of saving and capital accumulation, exchange and money, economic competition, and also economic inequality—all of them leading features of capitalism—can now be explored.

2. The Dependence of the Division of Labor on Saving and Capital Accumulation

Even before the development of money and monetary exchange, saving and capital accumulation are vital to the development of the division of labor. They are necessary to release people's labor from the immediate production of food, so that they can turn to the production of other things, including tools for producing food. In the absence of any saving and capital accumulation whatever, everyone's labor would have to be devoted almost exclusively to securing his next meal. With saving and capital accumulation, even if only in the form of stores of food, people can turn their attention to the production of other things. For example, primitive hunters or fishermen who have accumulated stocks of food can live off them while they set about constructing huts and also better means of hunting and fishing, such as bows and arrows and boats and nets.

The ability to carry on the production of things other than immediate food supplies is an obvious precondition of the development of the division of labor, in that without it there would be the production of essentially just one thing, in which virtually everyone would be engaged, namely, food for the next meal. Probably there would be some division of labor even at that level—for example, some members of a tribe might concentrate on chasing animals, while others concentrated on the actual killing of them. But a precondition of people specializing in the production of distinctly different products is the ability to carry on the production of such products, and here saving and capital accumulation are necessary in the case of every product whose production entails the lapse of more time than transpires between two meals. They are necessary insofar as people must have that second meal (or whatever else they normally consume) before their labor results in the consumers' goods they help to produce. Their ability to consume before their product is produced is possible only to the extent that savings exist.

As indicated, the accumulation of capital is also vital in raising the productivity of the labor of food producers, so that not everyone's labor is required in the production of food. It is only to the degree that fewer people are required to produce the food needed by all, that more people can devote their labor to things other than food, and thus the division of labor develop. The relationship between the productivity of labor in food production and

the division of labor is reciprocal. To the degree that the productivity of labor in food production rises, more people can be spared for other branches of production. The effect of the expansion of these other branches in turn is a higher productivity of labor in food production, because food producers are thereby enabled to work with the aid of more and better products of other branches of production—for example, farmers can work with the aid of more of the products of manufacturing.

Saving and capital accumulation, of course, are no less vital in the context of a monetary economy, as has already been shown. Closely connected with the fact that they are the source of the demand for factors of production is the fact that their existence is what enables producers to be paid within a reasonable period of time after the completion of their work. In the absence of savings and capital in terms of money, any significant division of labor would be impossible, because it would then be necessary for many producers to wait years, decades, generations, or even centuries before being paid.

Consider the case of automobile workers today. At present, like most other workers, they are paid after the completion of a week's work. Yet far more than a week goes by between the performance of the auto workers' labor and the time the auto companies are paid for the cars those workers help to produce. What makes this possible is the fact that the auto companies possess capital. They pay the wages of their workers week after week out of capital, and only months later do they recover the outlays of any given week in sales revenues.

Indeed, even most of the sales revenues of the auto companies are paid out of savings and capital. Most new-car buyers buy on installment credit. Under this arrangement a bank or some other financial institution advances them the funds to buy their car, and they then pay off over a period of two to four years. In the absence of this capital and the capital of the auto companies, auto workers would have to wait in excess of two to four years before being fully paid for their work. And the same would be true of all the suppliers of the auto companies, such as the steel and tire companies, and the like. They would all have to wait to receive the installment payments from the car buyers.

In the absence of capital in the hands of steel and tire producers as well as auto producers and companies financing automobile purchases, the period for which companies and workers would have to wait to be paid would be increased still further. The workers employed by the steel and tire companies, and the suppliers of the steel and tire companies, such as iron mining concerns and rubber plantations, would all have to wait the full period of time waited by the auto workers *plus* the period of time that presently elapses between the payments by the steel

and tire companies and the receipt of sales revenues by these companies. The consequence of a still further lack of capital, this time by the iron mining concerns and rubber plantations, would, of course, be to make the plight of the employees and suppliers of these concerns even worse. And so it would be with every further stage of remove from the production of automobiles.

The full magnitude of the time factor in production becomes clear if we begin to look at the equipment and buildings used by an industry. For example, the auto industry's equipment probably lasts on the order of a generation; its factory buildings, on the order of two or three generations. If the auto industry did not possess capital funds to pay for that equipment and those buildings, the suppliers of the equipment and the construction contractors involved would have to wait to be paid out of the sales revenues earned by the auto companies over a period of from one to three generations.

In the absence of capital in the hands of the equipment makers and construction contractors as well, it would be their employees and suppliers who would have to wait this period of time to be paid. These workers and suppliers would also have to wait the additional time that transpires within these industries in the making of the equipment and the construction of the buildings. Indeed, those involved in the production of such things as construction equipment and in the building of factories for producing machinery and construction equipment would be confronted with periods of waiting time that extended beyond their life spans and their children's life spans. This would be the case, for example, where the steel girders used to erect an auto plant that will last fifty years come from a steel mill that is itself fifty years old and was constructed with materials produced in a previous plant that at that time was fifty years old. Here a time span of a hundred and fifty years is involved between the performance of labor and the payment by an ultimate consumer.¹²

In the absence of capital in the hands of business enterprises, there would simply be no way for heavily time-consuming processes of production to exist. Even substantial savings in the hands of workers would not be sufficient. We might imagine a few workers with enough savings to enable them to work for a few years before they were paid, but we certainly cannot imagine an economic system in which there are workers willing to work and not be paid in their lifetimes, indeed, in which payment would not occur even in the lifetimes of their children or grandchildren.

In order for the division of labor to exist in an extensive temporal succession, in which groups of workers produce tools or materials taken up by other, succeeding groups, in processes extending over long periods of time,

it is absolutely essential that there be capital funds, so that each group can be paid within a reasonable time after completing its work. The existence of capital funds introduces a necessary *division of payments*, so to speak, that corresponds to the temporal division of labor.

In the absence of capital funds, there is only one source of payment—the ultimate, final consumers, whose outlays lie months, years, generations, even centuries in the future. With the existence of capital funds, there is immediate payment, however far in the future the expenditures of the ultimate, final consumers may lie. Only because of the existence of capital funds can the division of labor exist in an extensive temporal succession.

And, as will be shown later in this book, the greater is the accumulation of capital funds relative to consumer spending, the greater is the employment of labor serving the achievement of temporally remoter ends. This means, the greater is the accumulation of capital funds relative to consumer spending, the more does labor in the present serve consumption in the future, and the more is consumption in the present served by labor performed in the past. As will be shown, the effect of labor being able to be employed for temporally more remote ends is to accelerate the rise in its productivity.¹³

The existence of division of labor in the form of a temporal succession of producers can be termed the vertical aspect of the division of labor. It is important to realize that saving and the provision of capital it makes possible also vitally contribute to the division of labor in what may be termed its horizontal aspect—that is, the extent to which it can be carried at any given stage of production. The extent to which the division of labor can be carried at any given stage of production depends on the scale on which production is carried on at that stage. For example, if automobiles are produced on a scale of only one or two a day in a given establishment, there is obviously room for far less division of labor than if they are produced on a scale of hundreds or thousands a day in a given establishment. In the former case, it is impossible to make a full-time job, or anything approaching a full-time job, of any individual operation that requires only a small amount of labor per unit of output. But in the latter case, it becomes possible to make full-time jobs of individual operations requiring quite small amounts of labor per unit of output.¹⁴

What is important to realize here is that in order for production to be carried on, on the larger scale, *more capital is required*. To be able to produce automobiles on a scale of hundreds or thousands per day rather than one or two per day, vastly more capital is required. In this way, more capital becomes the precondition for the extension of the division of labor in its horizontal, as well as vertical, aspect.¹⁵

Thus, saving and capital accumulation lay the groundwork for the division of labor in four ways. They make possible the production of goods other than the food required for the next meal. They raise the productivity of labor in food production, so that people can be spared for other branches of production, which makes possible further increases in the productivity of labor in food production. They make possible a division of payments, so that the time which elapses between the performance of labor and the receipt of payment by the producers is relatively short, no matter how long is the time which must elapse between the performance of labor and payment by the ultimate, final consumers. Finally, they provide the foundation for larger-scale production and thus the basis for carrying the division of labor further at any given stage of production.

3. The Dependence of the Division of Labor on Exchange and Money

The division of labor presupposes the ability to make exchanges, and the existence of an extensive division of labor presupposes the existence specifically of money and monetary exchange. The necessity of exchange and money is implied by the fact that in a division-of-labor society each person produces or helps to produce just one or at most a very few things, and is dependent for his consumption on the goods and services produced by a vast number of others. In these circumstances, some mechanism must exist whereby the products of each can be channelled to others and the products of others channelled to each. Exchange is that mechanism. A division-of-labor society requires exchange on a massive scale, as a constant, major feature of economic life. In a division-of-labor society, all or practically all of everyone's production must leave him through the process of exchange, and all or practically all of everyone's consumption must come to him through the process of exchange.

But a special kind of exchange is required to make this possible. The direct, barter exchange of goods for goods is not sufficient. In order for exchange to take place under such conditions, a so-called double coincidence of wants must exist—that is, each of the two parties must possess what the other desires and desire more what the other possesses. This condition very often, indeed, usually, cannot be realized. For example, a producer of ball bearings, steel girders, or sulfuric acid desires food possessed by grocers or farmers. Yet few or no grocers or farmers desire ball bearings, steel girders, or sulfuric acid. If exchange were confined to barter, producers of such goods could not live by producing them, and so people would not produce them. The economic system would thus have to get along without such vital goods.

Indeed, hardly anyone could live by producing the goods or services he now produces, because hardly anyone produces things that are consumed to any significant extent by those who supply him. (The reader should consider to what extent the goods or services he produces or helps to produce are consumed by those who regularly supply him.)

And even where people might be engaged in producing things that would be desired by their suppliers, it would still be impossible to effect many valuable exchanges. For example, the producers of television sets, or the builders of houses, desire bread and shoes; and the producers of bread and shoes desire television sets and houses. Putting aside such obvious problems as the particular houses probably being in the wrong location for the bread and shoe producers, there is the very serious problem of how could the producers of bread and shoes *make change* for the producers of television sets and houses when the latter wished to purchase a loaf of bread or pair of shoes? Would they require them to accept hundreds or thousands of loaves of bread or pairs of shoes? Also, how could the producers of the television sets or houses pay their employees? With a fraction of a television set per hour? With a piece of a house per week? With the change they received in the form of loaves of bread or pairs of shoes?¹⁶

It might be thought that a series of indirect exchanges could provide a solution—that if the goods for which a product was exchanged were not of the kind desired by those from whom one wanted goods oneself, then one could reexchange these goods for goods that were in fact desired by those from whom one wanted goods oneself. But this could not actually provide a solution. A producer of ball bearings or sulfuric acid would probably acquire quantities of goods that ball bearings or sulfuric acid helped to produce. (A producer of steel girders, however, would immediately confront a problem of indivisibilities, in that he could not acquire a fraction of a building or bridge.)

Putting the problem of indivisibilities aside, it would be necessary to engage in an enormous series of exchanges, spanning who knows what distances and time intervals, if one were to assemble the various goods that even just a few of the producers desired from whom one wished to obtain goods oneself. To obtain the things he now does, the producer of ball bearings, for example, would have to reexchange the products he received for his ball bearings for the collections of goods desired by all the various suppliers of the consumers' goods he now obtains, from his grocer and landlord to his physician and travel agent. He would also have to reexchange them for the collections of goods desired by all the various suppliers of the means of production he uses in producing

ball bearings, namely, all his suppliers of materials, equipment, fuel, and labor services. The same would be true of the producers of virtually *all* goods, whose output now goes to people other than those from whom they receive goods and who are supplied by people other than those whom they supply. The problem here is that the *costs* of indirect exchanges, in terms of the time and effort that would have to be spent in effectuating them, would be too great to make the system practicable.

Thus, an economic system operating under the constraints of barter exchange would obviously offer only very limited opportunities for division of labor and would thus be extremely primitive. In essence, to live in such an economic system, one would either have to be a farmer or produce the kinds of things that could be readily exchanged with farmers, such as blacksmithing services.

What is required for the existence of a division-of-labor society is the existence of *money* and *monetary exchange*. Money is a good readily acceptable in exchange by everyone in a given geographical area, and is sought for the purpose of being reexchanged.¹⁷ Of course, one of the properties of money, which helps to make it universally acceptable, is its divisibility into small units.

With money, those for whom the individual produces and those by whom he is supplied can be, and almost always are, different and distinct parties. With money, a process of indirect exchange takes place about which no one need be concerned—it takes place virtually automatically and without cost. Each produces for others, though not the others by whom he is supplied. The individual produces for anyone who has money to offer, and then uses the money to buy from anyone who has the goods he wants. With the existence of money, the producers of ball bearings, steel girders, and so on sell them for money to whoever wants them and has money to offer for them, and then they turn around and spend the money in buying food or whatever else they may wish, from whomever they choose. Everyone works in his particular specialization, is paid money, and buys from all manner of people who do not at all consume the goods or services that he himself produces.

With money, the producers of television sets and the builders of houses can easily obtain items as small as a loaf of bread or pair of shoes, because they sell their products for sums of money, which in turn are divisible into parts as small as the price of a loaf of bread or a pair of shoes. The employees of these producers are likewise easily paid out of capital funds.

In these ways, money radically enlarges the opportunities for specialization. It makes specialization possible not merely in a comparative handful of cases, but universally.

Closely related to the previous discussion of the price

system, the use of money also solves another problem that would otherwise be insoluble and prevent the existence of a division-of-labor society. Namely, it makes it possible to perform economic calculations and thus economic comparisons. Without the use of money, a productive process would show only a variety of physical means of production at the beginning and some physical product at the end. For example, it would show at the beginning quantities of building materials, equipment, and goods exchanged for labor services, and at the end a finished building.

In such circumstances, it would be impossible to determine if the product represented a gain or a loss of wealth, because one would be comparing quantities of different kinds, with no common denominator in terms of which to add them or subtract them.¹⁸ One could not even answer such usually simple questions as which represents the higher wage or price? This is because, without the use of money, these questions would have to be posed in such forms as, which is more, a dozen eggs plus a loaf of bread plus a pair of shoes or two shirts plus a blender? But with the use of money, producers are able to compare the money value of their outputs with the money value of their inputs. They can also compare the costs of using different methods of production, the profitability of the different branches of production, and the remuneration of the various occupations. All of this is vital if production in the various branches of the division-of-labor system is to be properly coordinated and not collapse into chaos.

Guidance by monetary calculations and comparisons, in contrast, provides an objectively valid standard for economic behavior.¹⁹ This is because following this standard enables the individual actually to increase the wealth at his disposal. For example, if the purchasing power of money has not significantly declined in the interval, selling a building or any other product for a larger sum of money than the sum of money one has previously expended to produce it, means that one really does increase one's command over goods and services, for one now has the means of buying a larger quantity of them than before. Similarly, using a lower-cost method of production in place of a higher-cost method, buying anything at a lower price rather than a higher price, and earning a higher profit or wage rather than a lower profit or wage—all of these things in fact serve to increase the quantity of goods and services one can obtain in the market.

Thus, the existence of money is vital to the existence of a division-of-labor society, in that it makes possible economic calculations and thus economic comparisons serving as an objectively valid standard of economic behavior, as well as radically widens the possibilities for

specialization.

On the basis of what has been shown concerning the importance of money, it should be obvious what ignorance and injustice underlie the utterance that money is "the root of all evil." It would be far more correct and reasonable to argue that money is the root of all good. It is an essential root of the division of labor and of all the benefits to human life that flow from the division of labor.²⁰ The destruction of money would mean nothing less than the destruction of the division of labor and thus of modern material civilization. It would mean radical depopulation and utter impoverishment for whoever remained alive.²¹

The notion that money is the root of all evil finds expression in the alleged moral ideal propounded by the Communists of "from each according to his ability to each according to his need" and in the accompanying resentments against the necessity of earning money and against the great prominence accorded to the earning and spending of money in a capitalist society.²²

Those who hold the antimoney mentality, and who yearn for goods simply to be "free" for the taking, have apparently not stopped to consider what the alternatives to money are. The alternatives can only be either the absurdly cumbersome procedures of barter, which would make the acquisition of goods far more difficult or altogether impossible, or, worse, having to go naked into the forest to hunt and gather what little nature offers to human beings without any mechanisms of exchange at all—namely, a handful of nuts and berries (if others have not appropriated them first), or else the establishment of a totalitarian socialist dictatorship that is economically chaotic.

In a capitalist society on the other hand, by the relatively simple process of earning and spending money, the individual integrates his activities into a division of labor that has come to embrace the entire world and that stretches back in time to the point when man first began to employ previously produced goods in all of his productive activities. Thus, by earning money an individual is able to buy products that represent the application of the intelligence and knowledge of enormous numbers of other human beings both living and dead. He is thereby enabled to obtain goods in a way that is incomparably easier and more rewarding than any conceivable alternative.

Ironically, the earning of money could be substantially easier and less worrisome for many people than it now is, if only the enemies of capitalism had not in their ignorance succeeded in making it unnecessarily difficult. They have made it more difficult by such means as the imposition of minimum-wage laws and prounion legis-

lation. In raising wage rates above the free-market level, such measures have the effect of reducing the quantity of labor demanded below the supply available and thus of preventing people seeking to earn money from becoming employed and thereby earning it. In the absence of such measures, not only would employment and thus the earning of money be readily possible for everyone, but also costs of production and prices would be correspondingly lower. This last would mean that the buying power of the money earned more easily as the result of lower wage rates would be increased. Thus, the lower wage rates needed to secure full employment and the consequent ease of earning money would not imply any corresponding reduction in the goods a worker could obtain by virtue of his labor. Indeed, the goods the average worker could obtain would almost certainly be greater, precisely because of everyone who wanted to work being able to work and thus not having to be supported by others. Moreover, the productivity of labor would certainly rise more rapidly in the absence of government-supported labor-union efforts to sabotage it, such as preventing or delaying the introduction of labor-saving machinery. As a result, not only would the earning of money be substantially easier and less worrisome, but it would also be substantially more rewarding in terms of the goods it brought.²³

4. The Dependence of the Division of Labor on Economic Competition

As explained in Chapter 4, a major source of the gains from the division of labor is that the production of everything tends to be carried on by those who are able to do it best. Economic competition is the process of establishing who is able to produce things best.

The significance of economic competition for the division of labor is actually even wider than this statement may suggest. It is the process that establishes not only which individuals are best suited in the eyes of the market for all the various occupations, from wealthy businessman on down to janitor, but also which products are best suited for any given market, and which technological methods are best suited for the production of any given product. (This last embraces, for example, such choices as machine versus handicraft production, larger-scale production versus smaller-scale production, using copper versus using aluminum as a material, or coal versus oil as a fuel, producing in one geographical location rather than in another, and so forth.) Thus, economic competition is the process of determining the organization of a division-of-labor society with respect to the choice of products for markets and the technological methods of producing any given product, as well as of

persons for occupations.

Economic competition is necessary because the most efficient form of organization of a division-of-labor society is not automatically known. Also, it is subject to constant change, as new products and methods of production are discovered and old ones must be abandoned, as individuals' personal knowledge and preferences change, as capital is accumulated or decumulated, as the size and composition of the population changes, as new mineral deposits are found or old ones exhausted, and as soil and climate conditions change. In a free market, those who have differing opinions about which product is best suited for given customers, which method is most appropriate for producing a given product, or who is best qualified for a given job, come forward and submit their goods, their investments, and their talents to the judgment of the markets in which they seek to operate, and succeed or fail according to the judgment of those markets. (The judgment of a market, of course, is never final, in that individuals are always free to make further appeals to it, and again and again succeed in swaying it to their side when they have something better to offer.)

Thus, economic competition, far from representing any kind of antisocial phenomenon, as its critics claim, is a highly positive social phenomenon. It is an essential mechanism of organizing production under the division of labor, and thus an essential mechanism for improving the efficiency of the social cooperation which the division of labor represents.²⁴

Consistent with our earlier discussion of the price system, economic competition, or, more correctly, the *freedom* of such competition, is necessary to a division-of-labor society in a further respect as well. Namely to prevent it from being put at the mercy of the arbitrary demands of particular categories of producers.

By its very nature, a division-of-labor society vitally depends on the work done by various small minorities of people constituting particular categories of producers. In many cases, as the result of the government's intervention into economic activity, coupled with its refusal to enforce ordinary laws protecting individual rights, such minorities have been able to coerce the rest of the society into meeting their arbitrary demands, on pain of a breakdown of the economic system. One has only to think of the consequences of prolonged strikes in such fields as transportation, steelmaking, coal mining, electric power production, and even garbage collection—and the terms on which such strikes are almost always settled.

The existence of such cases is the result of violations of the freedom of competition by or on behalf of labor unions. In practically every country, the unions have succeeded in having laws enacted that greatly restrict the

employment of workers taking the place of strikers. For example, for many years, striking workers in the United States were held by law virtually to *own* their jobs, which had to be held open for them even though they refused to work, on pain of the employers having to pay triple back wages to the strikers in damages. (At the time of writing, efforts are underway in Congress to reimpose such conditions.) In addition, where replacement workers for strikers are legally allowed to work, the unions are able to practice violence and intimidation against which there is little or no legal recourse. For it is almost impossible to obtain legal protection against so-called mass picketing, which is inherently intimidating, and the police and district attorneys rarely enforce the laws against assault and battery and property damage when it comes to union violence.²⁵ The recent strike against *The Daily News* in New York City, in which some newsstands were actually set on fire in efforts to intimidate vendors into not selling the newspaper, and in which no arrests were made, is a glaring illustration of this fact. For further illustration, one has only to recall any of dozens of news pictures of mobs of burly workers blocking factory gates during a strike and the reports of slashed tires, shootings, and bombings that so frequently accompany strikes, and the fact that rarely if ever does any legal action take place against the perpetrators. In these ways, the unions and the government have succeeded in prohibiting freedom of competition in the labor market and thus in compelling the entire rest of society to give in to whatever arbitrary demands the unions in various critical branches of production may choose to make.

While this is a subject that requires a much fuller discussion, it can be said that the freedom of competition would be a sufficient guarantee against arbitrary demands by business firms as well as wage earners—even in cases in which the result of competition might be the establishment of just one company in a particular branch of production, such as one electric power company or one gas company in a given town. The freedom of competition would permit the entry of a new electric or gas company if the existing one's rates became excessive, and this fact would operate as a powerful check on the rates charged by the existing company. Also, in cases such as these, it is almost certain that different suppliers would compete with one another in terms of offering the customers in a given area long-term contractual guarantees concerning rates and service, so that when a company did succeed in becoming the sole supplier, it would operate under the terms of such a contract and not be able to impose arbitrarily high rates even temporarily. Under such an arrangement, an excessive rate or price would certainly not mean one that was arbitrarily increased by

a supplier, but, at most, one that failed to reflect improvements in efficiency made by other, potential suppliers. But even this situation could not long exist, if others possess the legal freedom of entry into the field.²⁶

5. The Dependence of the Division of Labor on the Freedom of Economic Inequality

A division-of-labor society depends on the institution of economic inequality, insofar as the latter results from the process of economic competition or, more broadly, from individuals freely engaging in production and exchange, whether they are in competition with one another or not.

Economic inequality inexorably emerges from the freedom of the individual to pursue his own prosperity and to keep as his own whatever he achieves. It emerges simply because not everyone is equally intelligent, talented, ambitious, or hardworking, or saves as great a proportion of his income. In effect, it emerges as the consequence of different individuals enacting different degrees of economic causation.²⁷

A division-of-labor society depends on economic inequality in the sense that it depends on individuals being free and motivated to produce. The abolition of economic inequality would mean the abolition of all connection between an individual's efforts and his income. It would be tantamount to the abolition of causality in the receipt of income.

To understand why this would be the result, imagine that a group of just ten people were formed whose members agreed to share equally all the income earned by each of them. Now imagine that a member of this group found a way to increase the income he earns by some given amount. Since he has to turn it over to the group and share it equally with the other nine members of the group, the personal benefit which he would obtain would be only *one-tenth* of that amount.²⁸

If the group consisted of a thousand people, then any individual who increased or decreased the income he earned by any given amount, would personally experience a gain or loss of only *one-thousandth* of that amount: he would personally gain or lose only one dollar for every one thousand dollars by which he increased or decreased the income of the group. If, as the egalitarians desire, the group consisted of the whole population of the United States or of the world, then for any given amount by which an individual increased or decreased the income of the group, he would increase or decrease the income available to him personally by only *one 250-millionth* or *one 5-billionth* of that amount.

It is obvious that once the size of the egalitarian group becomes substantial—probably anything much in excess

of ten—no significant connection can exist between what an individual produces and what he receives. And, what is also very important, no significant connection can exist between what an individual produces and what *any other particular individual receives*.

In a group as small as ten, say, especially if it consists of close friends and relatives, an individual might rationally consider the effect of his actions on the income available to the other members of the group and give it substantial weight in deciding how much to produce. But in any large group, the individual loses the power significantly to affect the income available to any other individual, as well as losing the power significantly to affect the income available to himself. In a group of a thousand, a million, or a billion, nothing the average individual does can significantly affect the income received by his wife and children or parents and friends; even their combined share is an insignificant part of the group's total income. Nothing he does can have any significant effect on the income of the group as a whole or, therefore, on any given proportion of that income, for he is only one among many, and his production, a small part of the total production. In collectivizing his product and spreading it over a large group, egalitarianism destroys the ability of the great majority of individuals to achieve results that are of significance *to anyone*.

The average person is capable of accomplishing results that are large in relation to himself, and large in relation to his immediate family. But very few people are capable of accomplishing results that are large in relation to significantly greater numbers of people. It is as though egalitarianism, seeing that individuals had legs easily strong enough to support their own weight, demanded that each individual's legs had to support the weight of the whole human race as the requirement for his being permitted to walk. To make it the job of the individual to improve his own life and well-being only insofar as he equally improves the life and well-being of everyone else in the country or the world is a demand that is fully comparable.

If implemented, it would give everyone the incentive to do as little as possible. In the same way that doubling one's production, if that were possible, would increase one's own income by only one 250-millionth, if egalitarianism were practiced on a national scale—or by one 5-billionth, if it were practiced on a world scale—and thus would not be undertaken, so getting away with not producing at all would reduce one's own income only by that amount.²⁹ Increasing one's production would not be of perceptible benefit to anyone, and decreasing it would not be a perceptible loss to anyone. As a result, everyone would have the incentive to do nothing.

It should be obvious that equality of income implies

forced labor—because, as shown, it eliminates the earning of income as an incentive to work. If people are to work without income as the incentive, the only remaining means of getting them to work is force.

It is true that there are other positive incentives for working besides income—such as the enjoyment of the work itself. But for the great majority of jobs, this factor exists in a form that is closely related to the earning of income and is largely felt only after the work is completed and the satisfaction of supporting oneself can be experienced. For example, no one digs ditches, hauls garbage, mines coal, works on an assembly line or in an office, or is even president of a bank, for the sheer love of his work, apart from all connection with the income it brings him. And even in the cases in which the work all by itself may really be a source of pleasure—for example, in the arts and sciences—this would not be sufficient to induce the amount of work that is presently done and that only the earning of income elicits. For example, I personally very much enjoy lecturing on economics and would want to continue my teaching career even if I were a millionaire and did not need the income from it. But instead of teaching two or three classes every term, I might want to teach only one class every other term. In the absence of personal material incentives, the only way of inducing any significant amount of work is by means of force.

There is an exception to the inability of individuals to achieve perceptible results in relation to large groups. This is the case of individuals of unusually great ability. A great scientist, inventor, or businessman is capable of increasing production so greatly that the whole world can experience a perceptible benefit. Yet this exception certainly does not represent a case in which economic equality would be practicable. On the contrary, precisely this case presupposes the possibility of *very great economic inequality*.

No scientist, inventor, or businessman should be imagined to be motivated to devote his life to raising the standard of living of the world by one, two, five, or x percent in order that he may, as part of the process, raise his own standard of living by one, two, five, or x percent. That would be an absurdly bad bargain: to work so hard and achieve so much for the rest of the world and so little for oneself.

The main value that a scientist achieves is the intellectual satisfaction of making his discoveries. In his case, this may stand in the place of any very great material reward. But inventors generally require the prospect of substantial material rewards, or they will not devote the time and effort or go to the expense that is necessary to make an invention. And as for businessmen, who are the

ones who actually implement the work of scientists and inventors—who search out and perfect the inventions, and who often set the scientists and inventors to work in the first place—their work takes place for virtually no other reason than as the means of accumulating a personal fortune, and, indeed, is possible for the most part, only to the extent that they have already accumulated one. This last follows from the fact that only to the degree that businessmen possess capital are they able to implement their ideas—that is, to buy or build the necessary factories and machines, purchase the necessary materials and supplies, and hire the necessary workers. Ford, Rockefeller, and Carnegie, for example, could raise the standard of living of the world only in the course of accumulating their fortunes, and only on the basis of the fortunes they had already accumulated.³⁰

Thus, the whole foundation of individuals of exceptional ability being able to act on a scale that raises the standard of living of everyone is the existence of enormous economic inequality, in the form of their being able to accumulate personal fortunes both as the incentive and as the means for raising the general standard of living.

The demand for economic equality turns out to be opposed to causality in a double respect: in respect both to the incentives for production and to the means of production. It would deprive the average person of the incentive to produce by depriving his productive effort of virtually all effect on his own or any other individual's standard of living. It would deprive the exceptionally able person of the incentive to produce by making the effect of his productive effort on his standard of living too small and by depriving him of the material means of achieving very great productive effects in the first place.

It should be realized that economic inequality plays a vital role in connection with the institutions of saving and capital accumulation and economic competition. The highest incomes in a capitalist society are those earned by successful businessmen. Insofar as such incomes represent the earning of high rates of profit on capital invested, the greater part of them tends to be saved and reinvested as the means of accumulating a fortune. Fortunes are earned by earning a high rate of profit on a rapidly growing capital—a capital which grows rapidly because most of the high rate of profit is constantly reinvested.³¹ High incomes are also frequently of the kind that must be regarded as temporary or exceptional by their recipients—for example, the incomes of authors of best-selling books and of successful professional athletes and movie stars. If such people want to enjoy the benefit of their currently high incomes over the course of their whole lives, during most of which they will probably not earn comparably high incomes, they must

save a very substantial portion of them.³²

It is for these reasons that a close, observable relationship exists between relatively high incomes and high rates of saving out of income, and that attempts to restrict economic inequality must substantially reduce saving and capital accumulation.

The role played by economic inequality in connection with economic competition is that it profoundly influences the areas in which people choose to compete. For example, the fact that Mr. A the engineer earns substantially more than Mr. B the mechanic ensures that Mr. A will not compete against Mr. B for the job of a mechanic, even though he might make a much better mechanic. The inequality of income leads people to compete only in the areas of those of their talents that pay the most, and to abstain from competing in the areas of their talents that pay less. It operates, when necessary, to enable the less able actually to outcompete the more able, and thus it guarantees the less able a place in the economic system.³³

Economic inequality, of course, can also be the product of government coercion, as occurs under feudalism and socialism, or as the result of any other arrangement under which the government grants privileges or imposes arbitrary burdens.³⁴ This latter sort of economic inequality is of a radically different character and is not only totally unnecessary, but also positively inimical, to a division-of-labor society. This is the case because the government's establishment of such inequalities deprives producers of a more or less considerable part of their product or income and directly infringes their freedom to produce in the first place. In so doing, it deprives producers both of the incentive to produce and even, in varying measure, of the very possibility of producing. It deprives them of the very possibility of producing insofar as it establishes arbitrary economic inequality by means of monopolistic restrictions against their entry into various lines of production. It also deprives them of the very possibility of producing insofar as it appropriates their incomes and thereby reduces their ability to save and invest, which deprives them of the ability to purchase the means of production. At the same time, in giving their product or income to others or in bestowing monopolistic privileges on others, the government rewards nonproducers or less efficient producers. Thus, economic inequality based on government coercion is economically destructive.

The fact that economic inequality can be the result of coercion is the reason why I did not describe it earlier in this chapter as an institution to which private ownership of the means of production is essential, as I did in the cases of the price system, the profit motive, economic competition, saving and capital accumulation, and ex-

change and money. Private property and private ownership of the means of production are essential only to *earned* inequalities of wealth and income—that is, to inequalities arising out of differences in the ability and willingness to produce and save, where the freedom to own and use property is essential. By the same token, unearned inequalities of wealth and income—that is, inequalities forcibly imposed by the government—represent a violation of property rights and thus of the institution of private property and private ownership of the means of production. For they entail depriving people of their property or the freedom to use their property, including, of course, their means of production.³⁵

Thus it should be understood that at a fundamental level the case for economic inequality that I have presented is not at all a case for economic inequality *per se*, but only for the economic inequality that results from the existence of individual freedom and respect for individual rights. (Such inequality, of course, includes that which is based on inherited wealth insofar as the wealth was accumulated by means of production and saving under free competition and then must be maintained by the heirs in the face of free competition.³⁶)

In connection with the distinction between the sources of economic inequality, it is worth noting that economic inequality that is founded on economic freedom is accompanied by much less in the way of visible inequality than is economic inequality founded on the initiation of physical force. This is because, as I will show in Chapter 9, the economic inequality that is based on economic freedom, serves to raise the standard of living of all.³⁷ As a result, under economic freedom, even the poorest strata of society consume substantial and progressively increasing quantities of wealth. Thus, the inequality that prevails is not one of a contrast between those who are starving, half-naked, and living in hovels, and those who are fat, clad in furs, and living in castles, as is the case under feudal inequality, for example. Rather it is an inequality between those who are rich enough to drive Chevrolet or Ford automobiles, and those who are rich enough to drive Cadillacs or Rolls Royces. Under modern capitalism, everyone who works is well-fed, comfortably housed, and attractively dressed. Indeed, it often takes an expert to distinguish between the clothing worn by a well-dressed secretary and that worn by a millionairess.

Failure to realize that the economic inequality that results from economic freedom and capitalism is less extreme than the economic inequality that is based on the initiation of physical force, sometimes leads to the absurd conclusion that forcible restrictions on the freedom of economic inequality can promote prosperity. Thus one

compares the extreme inequality of semi-feudal societies such as Saudi Arabia, with the lesser inequality of relatively free societies such as the United States, and attributes the greater prosperity of the latter to their greater equality rather than to their greater freedom. The fact is, of course, that it is greater freedom which is responsible both for greater prosperity and for a less extreme degree of economic inequality, while forcible restrictions on the freedom of economic inequality only serve to undermine prosperity.³⁸

Egalitarianism and the Abolition of Cost: The Example of Socialized Medicine

In addition to encouraging people to do nothing, egalitarianism also leads them to demand everything. It is tantamount to the abolition not only of causality in the earning of income, but also of cost in the spending of income. To make something free to the individual and chargeable to the group as a whole, is to make the consumption of the individual virtually costless—both to himself and to every other individual.

Socialized medicine provides an excellent illustration of this principle. When visits to doctors are made free to the individual and chargeable to the taxpayers collectively, then each individual perceives the benefit of his going to a doctor, while he and every other taxpayer experiences a personal cost equal to the cost of the visit divided by the number of millions of taxpayers. In such circumstances, every individual is encouraged to take advantage of the situation and, as a result, the overall cost to everyone actually ends up greatly increasing.

What happens is this: A doctor's visit that might cost an individual fifty dollars, is passed on to, say, one hundred million taxpayers, to each of whom it costs a hundred-millionth of fifty dollars. But now, perhaps, two hundred million people each want to make five times as many visits to doctors, and so the total cost to everyone ends up being vastly greater than it would otherwise have been. Furthermore, the absence of cost to the individual patient is responsible for an enormous increase in the amount of medical tests, hospitalizations, and surgeries performed, which add even more to the cost of the system. And, of course, there is the substantial overhead cost added by the need for a large bureaucracy to administer the system.

Ironically, even though they pay vastly more, people end up obtaining *less* actual medical service than before. In large measure, the effect of the system is simply to make doctors' and other medical fees rise and to create shortages of doctors' time and hospital beds—as manifested in crowded waiting rooms and reduced time with the individual patient, and in waiting lists to enter hospitals. A large portion of the additional medical tests,

hospitalizations, and surgeries is actually unnecessary, and serves to prevent or delay the meeting of genuine medical needs. The measures adopted to deal with these problems, such as controlling doctors' fees and their methods of treatment, and thereby thoroughly bureaucratizing the field, ultimately make medicine unattractive as a profession and deter talented individuals from entering it. In addition, they frequently serve to deny necessary treatment to people, since the government has no rational method of determining what is the appropriate treatment in the individual case.

In what is perhaps the supreme irony of the system, in efforts to control costs, the government ends up actually *opposing advances in medical technology*. It comes to regard such procedures as the implantation of artificial hearts as a major threat to its budget. This is with good reason, since, by the logic of socialized medicine, everyone who needs it is entitled to demand a procedure as soon as it becomes recognized as practicable. The result of this is that the normal, free-market incentives which work to reduce costs before something becomes available to a mass market are not present under socialized medicine. Thus, for these reasons, advances in medical technology become feared and arrested under socialized medicine.

In addition, in further cost-containment procedures, the government begins to restrict or prohibit whole categories of procedures, from cosmetic surgery to bypass operations. Such procedures are excluded from the socialized system on the grounds that they are "non-essential" or "too costly relative to the benefits obtained" (benefits for the government). Thus, people who under private medicine could have obtained such procedures by spending their own money for them are denied the ability to obtain them. They are denied this ability because taxes to pay for the medical care of others, and simply to squander, drain them of the necessary financial resources. The possibility of obtaining the necessary procedures, of course, can also end up being prohibited outright, if the socialized system achieves a complete monopoly and decides not to perform the procedures or not to make them available to specific categories of individuals.

Along these lines, the government begins to deny medical care to those whom it regards as only "marginally valuable to society," such as the aged. From the perspective of the government's budget, medical care for the aged is a poor investment: the cost is high and the remaining ability of the aged to pay taxes is relatively small in view both of the limitation of their remaining years and of their possibly diminished capacity, or total lack of capacity, for working and earning taxable income. Thus it should not be surprising that under socialized

medicine in Great Britain, for example, bypass operations are made difficult to obtain for people over fifty-five years of age, and an elderly person who breaks a hip is likely to die before being able to obtain corrective surgery.

Thus, in an irony with truly ominous implications, the same system of socialized medicine which began in the United States largely as a means of financing the medical bills of the aged has the long-run potential of turning the aged into sacrificial victims. It has the potential not only of depriving them of all the advances in medical care that they could have obtained in a free market and of making them share in the general decline in the quality of medical care that must result from socialized medicine, but also of placing them in a position of helplessness, in which they are the mercy of a system which attaches little value to their lives.

The fact that socialized medicine has such results should not come as a surprise. It is a profound mistake to believe that there is such a thing as any form of free lunch from the government in the first place. And only someone very foolish indeed should be surprised that when the government buys him lunch it is not eager to increase its expenses on his behalf and thus is not willing to buy him a steak for lunch. He should not be surprised that the government will much more likely end up placing him on short rations, in order to have more funds left over for paying the bills for those whose needs it considers to have a higher "social priority." Thus, anyone who wants his medical care to be free by virtue of having the government pay for it, should not expect very much or very good medical care. He should rather expect his medical care and treatment to resemble that of the general care and treatment of an unfortunate child whose life has been entrusted to uncaring and potentially cruel stepparents. The state will likely prove just such a guardian of the aged. A child, of course, does not usually select such stepparents. The aged of today, in a state of knowledge below that which should be expected of children, are selecting such a guardian for themselves.³⁹

It should be realized that the collectivization of medical costs—an essential feature of socialized medicine—has existed for many years in the United States. It was brought into existence not only by the Medicare and Medicaid programs that date from the mid-1960s but also by unsound private medical insurance practices imposed by government intervention, and which date back to World War II. Like Medicare and Medicaid, and socialized medicine in general, most private medical insurance plans of the last fifty years give medical care the appearance of being free or substantially free to the user, and thus substantially increase the demand for it and its cost.

Such private insurance came into being as a substitute for socialized medicine and was greeted as a means of forestalling the enactment of socialized medicine. It was extended to a significant part of the population first through a World-War-II decision by the price-control authorities that while ordinary, take-home wages were subject to controls, employer-financed medical insurance for employees was not. And then, following the war, in the remaining years of the 1940s and in the 1950s, it was extended to the great bulk of the population by the contract demands of coercive labor unions, which most nonunion employers felt obliged to meet, as part of their efforts to remain nonunion. The growth of such insurance was also fostered by the fact that from the beginning employer contributions to medical insurance on behalf of employees was made tax exempt, while the payment of the same amount of compensation directly to employees has been fully taxable to the employees.

Government Intervention, Democracy, and the Destruction of the Individual's Causal Role

Essentially the same kind of destruction of causality as results from the establishment of equality of income or an equal sharing of costs among the entire population results from all governmental usurpations of power and responsibility. When, for example, the government comes to decide the manner in which individuals provide for their old age, or to decide matters pertaining to education, it destroys the ability of the individual to choose for himself.

The fact that the government may be subject to the verdict of democratic elections only serves to highlight this fact. Instead of signifying that nothing is wrong, because the government is still subject to the will of the people, the fact is that the power of the *individual* to determine his own life is submerged in that of an enormous mass of voters. True enough, under democracy if a majority of a voting population ranging from several hundred to a hundred million or more (depending on the level of the election—local, state, or federal) votes against an existing policy, the policy will likely be changed. But this does not mean, as the supporters of government intervention often argue, that the government is still “controlled by us.” As far as any individual is concerned, the government is totally out of control.

For example, when it comes to the use of savings in the so-called individual retirement accounts that the government supervises (let alone the use of savings siphoned off into the social security system), instead of the individual being able to decide for himself that he wants to use a portion of his savings to make the down payment on a home, he must wait until tens of millions of other citizens have become ready to join with him to bring

about this possibility. In the same way, instead of an individual set of parents being able to decide to send their child to an elementary school that is close to their home, they may have to wait until that possibility is established by means of a national election.

Thus, to the extent government intervention exists, even under democracy, the individual by himself is prevented from accomplishing what he wants to accomplish. His power to act as an individual causal agent is destroyed. For government control under democracy still means collectivization of the power to make decisions. And thus from the perspective of any individual the result for all practical purposes is as much a loss of the freedom of choice and the power to act as exists under dictatorship. Only limitation of the powers of government can secure individual freedom and the ability of the individual to act as a causal agent. Violations of individual freedom by democratic majorities are as much violations of individual freedom and the ability of the individual to act as those imposed by dictators.

Summary

The preceding sections have shown why the division of labor is entirely dependent on the institutions of capitalism. Section 1 showed how it depends on private property and private ownership of the means of production as the basis for enabling people to act and produce separately and independently of one another. Such independence is essential if people are to be able to take advantage of the fundamental facts underlying the gains from the division of labor, namely, that individuals possess separate, independent minds and separate, independent knowledge. This section showed that socialism and central planning are incompatible with the necessary intellectual division of labor that must exist in order to have rational economic planning. It showed why the existence of the price system is essential for such planning and both why the price system depends on the profit motive and the freedom of competition and why these two institutions in turn depend in turn on private ownership of the means of production. The section also showed why the price system depends on exchange and money and saving and capital accumulation and why they too are dependent on the institution of private ownership of the means of production.

Subsequent sections explained the direct dependence of the division of labor on the institutions of saving and capital accumulation, exchange and money, competition, and the freedom of economic inequality. Saving and capital accumulation were shown to provide the essential basis for making possible the production of goods requiring more or less considerable lapses of time between the

performance of labor and the appearance of the resulting product. Saving and capital accumulation were also shown to be responsible for initially raising the productivity of labor to the point where labor could be spared from food production for the production of other things, and then for making it possible for wage earners and suppliers to be paid within a reasonable period of time after the performance of their work, and, finally, to provide the foundation for larger-scale production and thus the basis for carrying the division of labor further at any given stage of production.

Exchange and money were shown to be essential to the channelling of goods from their producers to their consumers. The existence specifically of money and monetary exchange was shown to be essential to overcoming the problem posed under barter of the need for the existence of a double coincidence of wants as the precondition of an exchange. In overcoming this problem, the existence of money was shown to make possible a radical widening of the extent of the division of labor. Money was further shown to be vital to the existence of a division-of-labor society in making possible economic calculations and comparisons. The gross injustice of regarding money as the root of all evil was pointed out, along with other common errors found in the antimoney mentality.

Economic competition was shown to perform the vital function of determining the ongoing organization of a division-of-labor society with respect to the choice of which persons are to hold which occupations, which products are to be produced for which specific markets, and which technological methods of producing any given product are to be used. Economic competition, or at least the freedom of such competition, was also shown to be necessary to prevent a division-of-labor society from being placed at the mercy of the arbitrary demands of various vital industries or occupations.

Finally, the existence of economic inequality, resulting from unequal degrees of achievement, was shown to be essential to individuals being able to act as causal agents in accomplishing results, whether within a division-of-labor society or outside of a division-of-labor society. The alternative to such economic inequality was shown to be forced labor, as the only means of inducing people to work in the absence of economic incentives. In addition, such economic inequality was shown to play a major role in promoting saving and capital accumulation and in making it possible for the less able to compete with the more able. The imposition of equality in the meeting of costs was shown to be tantamount to the abolition of cost from the perspective of the individual user of a good or service. The destructive consequences of such impositions were explained, using socialized medicine as

an example. And then, government intervention in general, even under democracy, was shown to represent the destruction of the individual's ability to act as a causal agent, inasmuch as it requires that before the individual can accomplish what he wants to accomplish, he must first join with perhaps millions or tens of millions of others to make it possible.

PART B

ELEMENTS OF PRICE THEORY: DEMAND, SUPPLY, AND COST OF PRODUCTION

Before proceeding to the substance of price theory, it is necessary to deal with matters which occupy the major portion of most of today's courses and textbooks on the subject, namely, the concepts of demand and supply, and, in particular, their representation as curves. This material is included in this book in part for the benefit of economics instructors who are obliged to present a geometric analysis using such curves. It is offered in the hope that if they are otherwise inclined to adopt this book, they will not have to turn elsewhere in order to expose their students to such curves.

Frankly, while I believe that the ability to understand and visualize downward sloping demand curves, and vertical lines as representing supply, is of some significant value, I do not attach very great weight to geometrical analysis in economics. I share with von Mises the conviction that the substantive relationships of economics must all be explained by an essentially verbal analysis and that the drawing of such curves is mere byplay as far as real economic analysis is concerned.⁴⁰ I present my substantive, verbal analysis of price theory in the next three chapters of this book. Indeed, I believe that geometrical analysis using demand and supply curves masks some major confusions. The clearing up of these confusions is an important objective of the remainder of this chapter and is the main justification for including the extended discussions of the derivation of supply curves and of the prevailing confusions between the concepts of supply and cost of production. On a positive note, in the following pages I explain the various meanings that are attached to the words demand and supply, demonstrate why price and quantity demanded vary inversely, and present what is genuinely valuable in being able to visualize demand and supply curves.

The connection of the following discussions to my theme that the division of labor depends on the institutions of capitalism is perforce indirect. As I have already

indicated, the division of labor depends on the existence of the price system both for its successful functioning and, indeed, for its very existence. The following discussions are preliminary to the detailed demonstration of that proposition.

1. The Meaning of Demand and Supply

Perhaps no proposition of economics is more frequently uttered than that prices are determined by demand and supply. Yet in the history of economics, and to an important extent even at the present time, the concepts of demand and supply have had more than one meaning, which can make the above proposition highly ambiguous.

According to the classical economists, demand is to be understood predominantly as an amount of expenditure of money, such as \$1 billion, while supply is to be understood as an amount of a good or service offered for sale. On this basis, prices are to be conceived as formed by *the ratio* of the demand to the supply, with demand as the numerator and supply as the denominator, and to vary in direct proportion to the demand and in inverse proportion to the supply. The classical view of price determination by demand and supply is expressed in the formula

$$P = \frac{D}{S},$$

where P is the price, D is the demand, and S is the supply.⁴¹

The classical economists also frequently defined demand as “the will combined with the power of purchas-

ing.”⁴² Here demand is to be understood in terms of the goods or services one is actually able to obtain by virtue of the expenditure of money. While certainly not inconsistent with the view of demand as an expenditure of money, this is a different concept of demand. To avoid confusion, it is best to describe demand in this second sense as *real* demand, with the word “real” denoting the fact that the quantity of goods or services one can obtain for the money expended is essential.

As used in contemporary economics, the concepts demand and supply mean *the set of quantities buyers are prepared to buy or sellers to sell at varying prices, arranged in descending (ascending) order, all other things being equal*. Viewed in this light, the concepts refer to hypothetical schedules, which when diagrammed, appear as curves. Illustrations of such hypothetical schedules and curves appear in Table 5–1 and Figure 5–1 respectively.

In the usage of contemporary economics, the entire set of prices in Table 5–1, ranging from \$10 down to \$3, together with the entire set of quantities demanded at those prices, ranging from 100 up to 500, represents *one demand schedule—the demand—for the good in question*. Strictly speaking, the concept of the demand schedule embraces prices ranging from zero to infinity, proceeding by the smallest possible increments in price, and all of the quantities demanded at all of these prices. The demand schedule presented in Table 5–1, therefore, represents only a few selected points on the actual demand schedule.

When diagrammed, as in Figure 5–1, the demand schedule appears as the demand curve DD . (In Figure

Table 5–1
Hypothetical Demand and Supply Schedules

Price	Quantity Demanded	Quantity Supplied	Quantity Demanded II
\$10	100	500	250
9	125	325	300
8	160	275	400
7	200	200	500
6	250	150	600
5	325	100	725
4	400	50	850
3	500	0	900

5-1, in accordance with the usual practice, price is shown on the vertical axis, where it is labeled P , and quantity, on the horizontal axis, where it is labeled Q .) The curve results from drawing a line through the various point values derived from Table 5-1. Ideally, the curve would be drawn by plotting all the point values derived from a complete demand schedule. The demand curve of Figure 5-1, of course, represents a limited range of the demand schedule, and most of its values are derived by interpolation between the few selected values that were present in Table 5-1.

In the same way, the entire set of prices and of quantities supplied, ranging from \$10 and 500 units down to \$3 and 0 units, together with all prices and quantities supplied above and below these limits, represents *one supply schedule—the supply*—of the good in question. When diagrammed in Figure 5-1 on the basis of the selected data appearing in Table 5-1, the supply schedule appears as the supply curve SS .

Accordingly, in the usage of contemporary economics, a change in demand or supply does not refer to a change in the quantity demanded or supplied within a given demand or supply schedule, or along a given demand or supply curve. For example, the increase in the quantity demanded from 100 to 125, accompanying the fall in price from \$10 to \$9, is not described as an increase in demand, but merely as an increase in the quantity demanded within a given demand schedule or along a given demand curve. A change in demand or supply is

said to occur only when there is a *change in the schedule or curve*. For example, the column labeled “Quantity Demanded II” in Table 5-1 is said to represent an increase in demand. Here, the quantities demanded are greater *at the same set of prices*. A change in demand or supply is held to mean a change in the quantities demanded or supplied at the same set of prices, or, equivalently, a change in the prices accompanying the same set of quantities demanded or supplied.

The demand curve $D'D'$ in Figure 5-1 is an illustration of a shift in the demand curve. In contrast with the curve DD , it shows larger quantities demanded at the same prices, and higher prices offered for the same quantities. It is drawn higher and to the right of DD . By the same token, a fall in demand would be illustrated by a movement from $D'D'$ back to DD .

In the view of contemporary economics, determination of price by demand and supply means *determination of price by the intersection point of demand and supply curves*. A rise in demand is held to increase both price and quantity supplied by virtue of the higher demand curve intersecting the given supply curve at a point up and to the right on the latter. Similarly, a fall in demand is held to decrease both price and quantity supplied by virtue of the lower demand curve intersecting the given supply curve at a point down and to the left on the latter. Likewise, an increase in supply, is held to decrease price and increase quantity demanded, while a decrease in supply is held to increase price and reduce quantity

Figure 5-1
Hypothetical Demand and Supply Curves Based on the Data of Table 5-1

demand. (To show an increase in supply in Figure 5–1, the reader can draw in a new supply curve, down and to the right of SS , and more or less parallel to it, which would intersect either DD or $D'D'$ at a point down and to the right of the intersection point given by SS . Movement from that curve back up to SS could then be used to depict the effects of a fall in supply.)

The classical and contemporary concepts of demand and supply are in agreement concerning the direction of price changes resulting from changes in demand or supply: on both views, price varies in the same direction as changes in demand and in the opposite direction of changes in supply. Moreover, it should be noted that when the demand schedule or curve of contemporary economics *changes*, the change coincides with a change in demand according to the classical concept as well. For what is implied is a change in the expenditure of money for any given quantity of a good supplied. For example, on demand curve DD , the price corresponding to a quantity demanded of 400 is \$4; on demand curve $D'D'$, the price corresponding to this same quantity demanded is \$8. Thus, in the first case, demand in the classical sense is \$1,600 (400 x \$4) and in the second case, it is \$3,200 (400 x \$8). Whenever, there is a movement of the demand curve, a corresponding change in expenditure is implied for any given quantity of the good. This is implied by the geometry of the situation, because expenditure for the good equals any given quantity of it times the corresponding price indicated by the demand curve; insofar as the demand curve changes and thus the price

corresponding to the given quantity changes, the expenditure for the good must change to the same extent.

The classical and contemporary concepts of demand and supply come closest together in the usage of the Austrian school. In the view of the Austrian school, supply fundamentally means a given quantity of a good or service available for sale.⁴³ Thus, in essence, the Austrian school retains the meaning given the concept of supply by the classical economists. In geometrical terms, when the Austrian economists describe price as determined by demand and supply, they have in mind the kind of demand curve represented by DD in Figure 5–1, but a supply curve constituted by a vertical line drawn upward from the point on the horizontal axis (the quantity axis) that represents the given amount of supply available. This is shown in Figure 5–2.⁴⁴

In the Austrian view of things, depicted in Figure 5–2, the sellers are presumed merely to be prepared to sell their given supply of goods at the best price they can obtain, from zero on up.⁴⁵ This is because in the context of a division-of-labor economy, the sellers normally possess goods in such great quantities that most of their supply has zero marginal utility—zero personal value—to them. As a result, on the Austrian view, prices that are determined by supply and demand are determined on the basis of the valuations of “the marginal pair of buyers” alone.⁴⁶

What this means is that the marginal utility attached to the price of any good that is purchased must simultaneously be below the marginal utility of the last unit of the good purchased and above the marginal utility of one

Figure 5–2
The Austrian View of Demand and Supply

additional unit more of the good that potentially might be purchased. For example, it implies that if a supply of one million shirts of a given kind is to be met with a quantity demanded of shirts that is also one million, then the price of a shirt must be such that the marginal utility of the price of the shirt is simultaneously below the marginal utility of the one millionth shirt and above the marginal utility of a potential one millionth and first shirt. The marginal utility of the price of the shirt must, in effect, be sandwiched between the utility of the marginal pair of shirts, that is, simultaneously below the utility of the marginal shirt and above the utility of the potential first submarginal shirt (that is, of one potential additional shirt more).

This is the necessary condition of equalizing the quantity demanded of *any* good with any given supply of that good that is to be sold. The marginal utility attaching to the price being below the marginal utility of the good in question is the condition of all the buyers of the good finding its purchase to be the source of a gain and hence worthwhile. By the same token, the marginal utility attaching to the price of the good being above the marginal utility of a potential additional unit of the good is the condition of it not being worthwhile for anyone to attempt to purchase an additional quantity of the good, and thus of the quantity of the good demanded not being greater than the given supply available. Whenever a case exists in which a given quantity of a good or service is to be sold in a free market, its price will tend to be determined within the limits set by the valuations of the marginal pair of buyers—that is, the marginal utility attached to the good by the buyer of the marginal unit and the marginal utility attached to the good by the potential buyer of one additional unit more, that is, the first submarginal unit.⁴⁷

In this book, the concepts of demand and supply will be used both in their classical and contemporary—especially Austrian—significations. The classical concept of demand as an amount of expenditure of money will be found to be extremely useful when dealing with questions pertaining to the operation of the economic system as a whole. In that context, it can be related, via the quantity theory of money, directly to the quantity of money in the economic system, which will be shown to be its main determinant.⁴⁸ The fact that economy-wide, aggregate demand in the classical sense is determined primarily by the quantity of money in the economic system makes it essentially independent of changes in aggregate supply in the classical sense, which latter can be understood as operating in the face of a given aggregate demand and thus to result in inversely proportionate changes in the general price level. In dealing with demand at the level of individual industries and companies,

however—where in essence it is a matter of explaining the adjustment of a part of the economic system to the rest of the economic system—this book will make use of the contemporary, Austrian concept of demand. This procedure will not be found to be in any way inconsistent with the use of the classical concept of demand at the level of the economic system as whole. Rather, it will be found to reflect the fact that at the level of individual industries and companies *competitive elements* are present which are mutually canceling at the level of the economic system as a whole.

The difference in treatment ultimately comes down to the fact that at the level of the individual industry or company, demand in the classical sense cannot be taken as independent of supply in the classical sense. Changes in supply at this level represent changes in competitive conditions among the various firms and industries, which cause changes in the pattern of expenditure for their various goods and services. This is because a change in the supply of any one good, such as automobiles or copper, means a change in its supply relative to the supply of other goods and a change in its price relative to the prices of other goods. If the supply of the good in question increases, say, and does so in the absence of increases in the supply of other goods, the marginal utility of this particular good may fall precipitously because of its additional supply, thus leading to the amount of money spent to buy it being reduced. For example, while people almost certainly would like to have an additional supply of automobiles, they want them along with more and better housing and clothing, more travel and entertainment, and so on. Until they can have more of all of these things, they will not be prepared to accept merely an additional supply of automobiles except at disproportionately lower prices.⁴⁹ On the other hand, in many circumstances the lower price of the given good may enable it to compete more effectively with other goods serving the same purposes, as we shall see very shortly. To the extent that this is so, the amount of money spent to buy it will increase. Thus, while demand in the classical sense can be taken as independent of supply in the classical sense at the level of the economic system as a whole, it cannot be so taken at the level of the individual industry or firm. Hence, at this level, it is necessary to resort to the contemporary, Austrian concept of demand.

2. The Law of Demand

A fundamental proposition of economics, applicable both to the classical and to the contemporary, Austrian concept of demand, is *the law of demand*. This is the fact that *other things being equal, the quantity demanded of a good is the greater, the lower is its price, and the*

smaller, the higher is its price.

At the level of the economic system as a whole, the law of demand follows directly from the fact that the need and desire for wealth has no limit and that a fall in the prices of goods and services is all that is necessary to enable any given expenditure of money to purchase a larger quantity of goods and services. The fall in prices expands the buying power of any given amount of expenditure and is potentially capable of making it sufficient to purchase any volume of aggregate supply, however large.⁵⁰

At the level of the individual industry or company, however, a fall in any given price always means much more than the fact that the average of prices is now lower relative to the willingness and ability to spend money and thus that the same aggregate expenditure can buy a larger total of goods. As stated, it also means a change in the prices of individual goods and services relative to one another.

For example, an increase in the supply and fall in the price of cotton means a fall in the price of cotton relative to the price of wool and other goods that cotton can more or less satisfactorily be substituted for. As a result, the purchase of cotton becomes competitively favored over their purchase. For now, in purchasing it, one can accomplish the common objective for which cotton, wool, and all the other relevant substitutes are means, and do so without having to forgo as large a quantity of alternative goods as previously. A lower price of cotton relative to the price of wool means that if one buys cotton instead of wool, one still obtains clothing (albeit, of course, with the specific advantages or disadvantages associated with cotton) and can now do so while forgoing a smaller quantity of alternative goods than before relative to the quantity one must forgo to obtain clothing made of wool. This change results in an increase in the quantity demanded of cotton at its lower price, and a decrease in the quantity demanded of wool and of the other goods for which cotton is a substitute, at their given prices. In other words, the quantity demanded of cotton increases, and the demand for wool and the other goods for which cotton is a substitute decreases.

In the literature of contemporary economics, such a change in the quantity demanded of a given good as its price falls is described as "the substitution effect." This effect is equally present, of course, when the price of a good increases relative to the prices of the goods for which it can be substituted or which can be substituted for it.

As will become clear, the substitution effect is actually just a special case of the operation of the law of diminishing marginal utility. And I turn now to a demonstration of how the existence of diminishing marginal

utility explains why, other things being equal, the quantity of a good people are prepared to buy is greater at a lower price than at a higher price.⁵¹

The reason is that in order to purchase a good, people must attach greater marginal utility to the good than they attach to the price of the good. A lower marginal utility is attached to a lower price than to a higher price. This is because the price of a good is the measure of the alternative goods that must be forgone in order to purchase it. A lower price of any given good means that to be able to buy an additional quantity of it, the quantity of alternative goods that must be forgone in order to have the funds available to make its purchase is correspondingly reduced (assuming their prices are unchanged). Since, other things being equal, a smaller quantity of alternative goods represents a lower marginal utility than a larger quantity of alternative goods, this means that the marginal utility represented by a lower price is less than the marginal utility represented by a higher price. (The lower marginal utility of a smaller quantity of goods compared with that of a larger quantity of goods follows on the basis of all that was established about man's limitless need for wealth. If more wealth is better than less wealth, it must have more utility, and less wealth must have less utility.) Thus a lower price of a good means that in purchasing it, the marginal utility one forgoes in the purchase of other goods is less.

As a result, the marginal utility attached to a lower price tends to stand below the marginal utility of a larger number of units of a good than does the marginal utility attached to a higher price. The consequence is that the purchase of a larger number units is made advantageous at a lower price.

As illustration, imagine that an individual attaches marginal utilities of 40, 30, 20, and 10 to four successive units of given good. Imagine also that to the sum of \$100 he attaches a marginal utility of 50, and to the sums \$80, \$60, \$40, and \$20, he attaches marginal utilities of 35, 25, 15, and 5, respectively. Thus, at a price of \$100, he will not buy any of the good, because the marginal utility of its price, 50, stands above the marginal utility even of the very first unit of the good, which is 40. But at a price of \$80, the marginal utility of the price, now 35, stands below the marginal utility of the first unit of the good. And thus this individual will buy one unit of the good. And for every further \$20 reduction in the price, he will buy one additional unit, up to a total of four, because the lower marginal utilities attached to these lower prices stand below the marginal utilities of the successive units of the good.⁵²

The role of the different alternative amounts of wealth that different prices represent can be seen in the following example, which deals with the hypothetical demand

for radios. If the price of a radio is \$100, then the purchase of a radio implies that one must forgo the purchase of whatever else that \$100 might have bought—that is, an additional quantity or improvement in the quality of alternative goods that one consumes. In order to buy the radio, one must attach a marginal utility to it that is greater than the marginal utility one attaches to the \$100 in any alternative line of spending. Those who buy radios at the price of \$100 do attach a higher marginal utility to them than to the expenditure of the \$100 in any other line or lines. Those who buy two, three, or more radios at the price of \$100 attach a marginal utility to each of them that is above the marginal utility they attach to any other, alternative goods the \$100 price could buy. By the same token, those who buy no radios at the price of \$100, or who buy one radio but not two, or two but not three, and so on, do not buy the radio in question because they attach a marginal utility to it that is below the marginal utility they attach to the purchase of alternative goods with the \$100 in question.

If, however, the price of radios fell to \$90, say, then the quantity/quality of alternative goods that would have to be forgone in order to make possible the purchase of a radio would be correspondingly reduced. This would mean a reduction in the marginal utility that had to be forgone in order to purchase a radio. This lower, alternative marginal utility would now tend to stand below the marginal utility of an additional quantity of radios. In the face of having to forgo alternative goods purchasable with only \$90 instead of \$100, in order to secure a radio, there would be people who previously judged the marginal utility of a first, second, or third radio, or whichever, to be less than the marginal utility of its price, who would now decide that it was greater than the marginal utility of its price.

In this way, a lower price of any good, whether it has direct substitutes or not, acts to favor its purchase.

Indeed, as stated, the substitution effect is merely a special case of the operation of the law of diminishing marginal utility. When the price of one substitute falls relative to that of another, as is the case when the price of cotton falls and the price of wool stays the same, what creates the competitive advantage is precisely the fact that the marginal utility of the alternative goods which must be forgone in order to purchase the one becomes less relative to the alternative goods which must be forgone in order to purchase the other. This is what favors the cotton, namely, that by buying cotton rather than wool, one can still meet the common purpose, in this case having cloth or clothing, and yet have greater marginal utility in terms of other things than if one buys wool, because now one gives up less of other things to buy cotton.⁵³

There is another major aspect of the competition that is present at the level of individual goods and services. A fall in the price of any given good, whether cotton, radios, or whatever, also means that to whatever extent people were already prepared to be purchasers of the good, they can now purchase the quantity they would otherwise have purchased, for a smaller expenditure of money. This means they will have correspondingly more money left over for the purchase either of more of that good or more of other things that they desire. For example, if one otherwise would buy 10 yards of cotton at \$2 per yard, a fall in price to \$1.50 per yard makes possible the purchase of the same 10 yards for only \$15 instead of \$20. This makes an additional \$5 available for buying either additional cotton or additional quantities of other goods.

In contemporary economics textbooks, such availability of additional funds is called “the income effect.” The income effect derives its name from the fact that the funds made available by the fall in price of something one already buys is viewed as similar to an increase in income with the price of the good unchanged.⁵⁴ Thus, the additional \$5 made available as the result of the fall in the price of cotton that we have just imagined is viewed as the equivalent of a \$5 increase in income with the price of cotton unchanged.

The so-called income effect also operates in accordance with the law of diminishing marginal utility. When, for example, the price of cotton falls, it is considerations of marginal utility that determine how the additional funds made available will be used in the purchase of additional goods. The additional funds will be used to purchase those additional goods which have the highest marginal utility.

Thus, the effect of a fall in the price of anything on the quantity of it demanded can be viewed as the combined effect of two things. One is an increase in available funds that results from the saving in purchasing the quantity of the good that would have been purchased without the fall in price. The other is the enhancement of the good’s competitive position in relation to other goods.

These other, competing goods must be understood not only in the narrow sense of substitutes serving the same particular needs or wants, such as wool versus cotton, but also in the broader sense of goods in general, or combinations of goods, that compete in terms of their marginal utility for the expenditure of the same funds. A lower price of television sets, for example, is capable of drawing funds in competition with goods serving physically dissimilar needs or wants, such as housing or automobiles. This is because a lower price of television sets relative to housing or automobiles means that the marginal utility forgone in buying a television set is that

much lower relative to the marginal utility forgone in buying housing or an automobile. This enhances the competitive position of television sets vis-à-vis housing and automobiles.

The operation of the law of diminishing marginal utility, both in and through the substitution and income effects and otherwise, is responsible for the existence of the law of demand, namely, that, other things being equal, the quantity of a good that is demanded moves in the opposite direction of its price. In the last analysis, the operation of the law of demand, and of the underlying principle of diminishing marginal utility, is tantamount to the fact that a lower price makes possible the acquisition of more wealth, which is always desired.

The Concept of Elasticity of Demand

Elements of the preceding discussion point the way to what has become an exceptionally prominent concept in contemporary economics, namely, that of *the elasticity of demand*. The elasticity of demand is typically defined as the percentage change in the quantity demanded of a good divided by the percentage in its price. As its name indicates, the concept seeks to measure the “stretch” or “shrinkage” in the quantity of a good or service demanded relative to changes in its price.

Three categories of demand are distinguished according to their degree of elasticity: elastic, inelastic, and unit elastic demands. Each is judged by the effect of a price change on total expenditure for the good (or, equivalently, on the total revenue derived from its sale). If expenditure (revenue) changes in the opposite direction of price, the demand is said to be elastic at that point—the stretch or shrinkage in the quantity demanded outweighs the change in price. In the case of an elastic demand, more is spent in buying the good at a lower price than at a higher price, and when the price rises, less is spent in buying the good. Here the change in the quantity demanded outweighs the change in the price.

If, on the other hand, expenditure (revenue) changes in the same direction as the price, the demand is said to be inelastic at that point—the stretch or shrinkage in the quantity demanded is insufficient to offset the change in price. In the case of an inelastic demand, more is spent in buying the good at a higher price than at a lower price, because of the relative lack of stretch or shrinkage in the quantity demanded.

Finally, if expenditure (revenue) for the good remains the same when the price changes, the demand is said to be unit elastic at that point, which means that the change in quantity demanded accompanying the change in price precisely counterbalances the change in price. When demand has unit elasticity, the change in quantity demanded is *inversely proportionate* to the change in price—

for example, a halving of price is accompanied by a doubling of quantity demanded, a cut to a third is accompanied by a tripling, and so on.

By far the most important example of unit elastic demand, and, at the same time, perhaps the only example that is not essentially accidental and passing, is *economy-wide, aggregate demand*. As previously stated, the volume of expenditure in the economic system as a whole tends to be the same so long as the quantity of money in the economic system is the same. Any increases or decreases in expenditure for particular goods or services are accompanied by equivalent decreases or increases in expenditure elsewhere in the economic system.

For example, an increase in expenditure for cotton, resulting from the operation of a strong substitution effect accompanying a lower price of cotton, is accompanied by a decrease in expenditure for wool and other substitutes. A possible resulting increase or decrease in the expenditure for clothing as a whole in such circumstances (depending on the marginal utility of additional clothing in comparison with the marginal utility of additional quantities of other things) would tend to be accompanied by a counterbalancing decrease or increase in the expenditure for things other than clothing. In the same way, a possible decrease in the expenditure for cotton, resulting from the existence of a weak substitution effect when its price falls, tends to be accompanied by an equivalent increase in the expenditure for other goods that is made possible by the availability of additional funds stemming from the fall in the price of cotton.

The principle here is that while competitive elements entailed in the substitution and income effects cause the expenditures for the products of individual industries and companies to vary in response to supply and price changes, nevertheless, in the very nature of the case, these elements, being competitive, cancel out when the level of analysis is raised to that of the economic system as a whole. Competition for expenditure takes place only *within the economic system*, among the various industries and firms that make up the economic system. It does not take place between the economic system and anything outside of the economic system.

Now a total expenditure for goods that is constant essentially so long as the quantity of money in the economic system is constant, is one in which price changes are necessarily accompanied by inversely proportionate changes in quantity demanded. Geometrically, the aggregate demand curve has the property that the area under the curve (found by multiplying the quantity demanded times the price) is a constant. The curve is asymptotic to both axes.⁵⁵ Such a demand curve is shown in Figure 5–3.

Turning now to the very different case of elastic demands, important examples of an elastic demand are

Figure 5-3
The Aggregate Unit Elastic Demand Curve

provided by goods which are presently luxuries, beyond the reach of most people, and which price reductions would bring within their reach. Equally important examples are provided by goods which can easily substitute for other goods or be substituted for by other goods.

An example of the first kind was the automobile in the first decades of the twentieth century. Television sets and personal computers are more recent examples of the same type. In these cases, price reductions succeeded in opening up a mass market to the good, which resulted in the expenditure for the good being greater at the lower price than at the higher price. Possible examples of the second type, representing varying degrees of substitutability, are provided by the case of cotton versus wool, previously considered, beef versus chicken and pork, and steel cans versus aluminum cans and plastic and glass containers. The degree of substitutability, of course, is vastly greater between the products of companies within the same industry, such as the steel cans of U.S. Steel and the steel cans of Nippon Steel.

Examples of an inelastic demand arise in cases in which a good has achieved the status of a low-cost necessity. In such cases, in a prosperous country, price reductions are not likely to expand the quantity demanded very significantly, since the good is already probably being consumed at or close to the limit of its usefulness. At the same time, the quantity demanded will diminish only slightly, or even not at all, in the face of moderate price increases, since people will continue to be able to afford the good in virtually unchanged quanti-

ties and it will still be less expensive than the substitutes for it. Such goods as bread, wheat, potatoes, and salt are in this category.

The demand for a good will tend to be inelastic to the degree that the substitutes for it are poor or more expensive than it is. It will also tend to be inelastic in cases in which it is employed as a factor of production in combination with other, complementary factors of production and in which its price constitutes only a small portion of the total cost of producing the product or products in question. In the latter instance, a rise in its price raises the overall cost of production and price of the product(s) in a much smaller proportion. The consequent reduction in the quantity demanded of the product and thus of it, corresponds to this much smaller relative increase in the price of the product(s).

Both sets of conditions appear to describe the demand for a great many goods, such as ordinary nails and screws, silver and mercury, gasoline and heating oil, and most components or parts. Nails and screws, for example, both have poor substitutes and their price constitutes such a small fraction of the overall cost and price of the products into which they enter—houses in particular—as hardly to be noticeable. Thus their price could double or triple and produce very little effect on the quantity of them demanded.

The degree of inelasticity of demand for goods tends to diminish to the degree that time is available for making adjustments. For example, a rise in the price of heating oil will be accompanied by a greater reduction in quantity

demanded as time goes by and a larger proportion of furnaces are equipped to burn alternative fuels.

The concept of elasticity of demand helps to make possible the comprehension of such phenomena as the effect of labor-saving improvements in machinery on employment. From the perspective of the economic system as a whole, such improvements in machinery neither cause unemployment nor additional employment. They enable the same total amount of labor to produce a larger quantity of goods. But from the perspective of individual industries, such improvements in machinery can sometimes result in additional employment and sometimes in less employment. It depends on the elasticity of demand for the particular products.

If a labor-saving improvement in machinery occurs in an industry that is confronted with an elastic demand, the effect will be more employment in that industry and correspondingly less employment in other industries. The saving of labor per unit of product results in a reduction in cost of production and selling price that is accompanied by a more than proportionate increase in the number of units of the product demanded.⁵⁶ At the same time, the larger expenditure for the product in question necessitates a reduction in expenditure for other products in comparison with what such expenditure would otherwise have been. Thus, for example, labor-saving improvements in the automobile industry earlier in this century resulted in a vast increase in the number of people employed in the automobile industry. At the same time, they resulted in a vast decrease in the number employed in raising horses and growing oats—goods which experienced a major reduction in demand as the result of the growth of the automobile industry.

If a labor-saving improvement takes place in an industry that is confronted with an inelastic demand, the effect will be less employment in that industry and correspondingly more employment in other industries, which experience a rise in demand as the result of the release of funds from the industry where the labor-saving improvement occurred. For example, labor-saving improvements in agriculture are typically accompanied by a reduction in the number of people employed in agriculture and a corresponding increase in the number employed in industry and commerce. This is in response to less money being spent to buy farm products, and more being spent to buy the products of the rest of the economic system.

Regrettably, the major application of the concept of elasticity in contemporary economics has been in connection with a false theory of monopoly. The practical usefulness of the concept has been thought to lie with enabling ordinary private businessmen, who somehow allegedly possess monopoly power, to decide whether it is more profitable to produce a smaller quantity of a good

for sale at a higher price rather than a larger quantity available for sale at a lower price.⁵⁷

Two variants of the concept of elasticity have been developed, which are known as “income elasticity” and “cross elasticity” of demand. By income elasticity is meant the percentage change in the quantity demanded of a product divided by the percentage change in people’s incomes. By cross elasticity is meant the percentage change in the quantity demanded of a product divided by the percentage change in the price of one of its substitutes or complements—for example, the percentage change in the quantity demanded of aluminum divided by the percentage change in the price of copper, or the percentage change in the quantity demanded of automobiles divided by the percentage change in the price of gasoline or automobile insurance.

In the face of the construction of such concepts as income and cross elasticity, and of attempts actually to derive concrete measurements of the elasticity of demand, it must be pointed out that there is no such thing as any kind of constancy of elasticities. Elasticities of demand bear no resemblance to such physical measurements as electrical conductivity, specific gravity, or tensile strength, which scientists and engineers can determine for the various elements and compounds. For example, it is simply not the case that as there is a definite electrical conductivity of copper, there is a definite elasticity of demand for copper—or for anything else.

The elasticity of demand varies over the length even of a given demand curve for a good. For example, the demand for automobiles is highly elastic in the zone in which a change in their price either brings them within or places them beyond the reach of a mass market. But once the price of automobiles is low enough to achieve a mass market, further reductions in their price will be accompanied by less elastic responses in the quantity demanded. The demand for automobiles may very well become inelastic. It is possible that a given demand for a good could go through various zones of elasticity, depending on such things as its relationship to the price of various alternative goods at different points. It is possible to imagine a good that becomes a worthwhile substitute for a variety of other goods as its price declines, with its demand alternating between elasticity and inelasticity as it absorbs the market of a competing good and then must await a fall to a substantially lower price to come within range of competing against a further good.

Beyond this, *there is no constancy of demand curves themselves*. Movement along any given demand curve implies changes in the demand curves of a wide variety of other goods. Every time a fall in the price of a good increases the quantity of it demanded by virtue of making

it a more worthwhile substitute for other goods, the demand curves for those other goods fall. Every time a fall in the price of a good inaugurates the income effect, the demand curves for countless other goods rise. Changes occur *mutatis mutandis* every time the price of a good rises.

Demand curves change because of changes in the prices of complementary goods as well as substitute goods. For example, a rise in the price of gasoline reduces the demand for automobiles and for the labor and other factors of production used to produce automobiles. In effect, a rise in the price of any complementary good—that is, any good which must be used in conjunction with other goods to accomplish a definite purpose—represents a rise in the price of accomplishing the overall purpose. In the face of this rise in the overall price, there is a reduction in the quantity demanded of all of the complementary goods required for accomplishing the desired purpose. Since the individual prices of all of the complementary goods but one are unchanged, the fall in quantity demanded of them represents a fall in demand pure and simple. Obviously, the same point applies with the necessary changes to the case of a fall in the price of a complementary good.

Demand curves change because of changes in the price of any other good whatever insofar as the effect is a change in the expenditure for that other good. For a change in the expenditure for any good means offsetting changes in expenditure for other goods. Demand curves also change because of changes in the quantity of money and the level of money incomes, changes in knowledge, tastes, and preferences, and the discovery or invention of new substitutes or complements. All such changes entail changes in elasticities of demand along with changes in the demand curves. The belief in any kind of measurable constancy of demand curves or of elasticities of demand is a manifestation of the philosophical determinism and arrogance of mathematical economics described earlier.⁵⁸

Seeming Exceptions to the Law of Demand

The downward sloping demand curve rests on the bedrock of fundamental economic principles. The fact that, other things being equal, people will buy more of something at a lower price than at a higher price is not contradicted by zones of demand curves in which the quantity demanded does not increase even though the price decreases. In such cases, either a greater decrease in price is what is required to expand the quantity demanded further, or else the good is already purchased to the point of satiety—thanks to the price already being low enough so that the marginal utility attaching to the price is below the marginal utility of the last unit of the good for which any useful employment whatever can be

found. In these cases, of course, the effect of a fall in price is still to increase the quantities demanded (and the demands) of all manner of other goods, for whose purchase the lower price of the good in question makes the necessary funds available.

A seeming exception to the law of demand exists in cases in which the demand for a good depends in part on its already possessing a recognized high value in exchange. For example, the demand for gold and silver as a store of value, and ultimately for use as money, depends upon the fact that in their capacity as ordinary commodities they are already highly valuable. It is for this reason, that when people wish to hold buying power in the form of stocks of physical commodities, they turn to gold and silver rather than other metals: the comparatively high value of the precious metals means that they can be used to hold a given store of value in a smaller bulk, which is easier and less expensive to store and transport.

Similarly, the fact that precious metals, diamonds and other precious stones, and various furs already possess a high value as commodities adds to their suitability for being given as gifts: in addition to their physical properties, their existing high value bestows on them the ability to symbolize the importance of the recipient to the giver. In such cases, it is true, if the price of the good fell below a certain point, part of the demand for it would disappear. But this does not mean that people prefer to pay more, other things being equal, rather than less. In these cases, the decline in value would represent a loss of one of the good's useful properties. The case is comparable to the demand for anything else being less when one or more of its useful properties is impaired. So long as the good retains sufficient value to serve the purposes for which a high value makes it qualified to serve, then, within that zone, the quantity demanded varies inversely with the price in the normal, uncomplicated way. When and if the price declines to the point that the good ceases to be able to serve the purpose that depends on a high value, the case must be understood in terms of the good having been rendered of lower quality.

Thus, the fact that part of the demand for such things as precious metals, precious stones, and various furs would disappear if their value were substantially lower should not be regarded as a contradiction of the law of demand. It is no more a contradiction of it than the fact that, say, grapes which are unsuitable for being made into good wine are less in demand than those which are suitable for being made into good wine, or that cattle incapable of breeding are less in demand than cattle which are capable.

Cases of so-called snob appeal are also essentially similar. If one wishes to be in the company mainly of wealthy people, then restaurants and hotels that only

wealthy people can normally afford derive a further, useful property in the minds of some people by virtue of that fact. One may agree or disagree with these people's assessment of what is or is not useful or desirable, but one must recognize that their behavior does not contradict the law of demand. So long as the price charged is within the zone of being high enough to restrict the clientele in this way, the normal relationship between price and quantity demanded prevails. And when the price charged falls below this zone, the usefulness of the good is reduced from the perspective of these buyers.

Finally, the law of demand is in no sense contradicted by observations of the fact that over time higher prices are frequently accompanied by increases in the quantity of a good that is demanded. Such results are precisely the effect to be expected from increases in demand—that is, of an upward shift of the demand curve. Increases in demand for this or that good or service can, of course, occur at any time. However, since the abandonment of the gold standard in the United States in 1933, substantial and practically universal increases in demand have become the norm, because of rapid increases in the quantity of money. It should not even be necessary to mention such obvious facts but for the existence of attempts to derive demand curves on the basis of alleged empirical observations.

The Derivation of Supply Curves

While the case for the downward sloping demand

curve can be taken as unexceptionable, the same is most certainly not true of the case for the upward sloping supply curve that is presented as typical by contemporary economics textbooks.

It might appear that such a case could be made by working the law of diminishing marginal utility in reverse. For example, it could be argued that a farmer who owns five horses will need a higher price to be willing to part with his second horse than with his first horse, and a still higher price to part with his third horse than with his second, and so on. For as the number of horses remaining in his possession decreases, the marginal utility he attaches to each remaining horse increases. And since the marginal utility he attaches to the price he receives for a horse must exceed the marginal utility he attaches to any horse he sells, the rising marginal utility of his diminishing supply of horses could be taken to imply a need for a rising price of horses as the condition of his offering a larger quantity of them for sale. The same principle could then be applied to all other suppliers of horses and to suppliers of all other goods. On this basis, a case might be thought to exist for assuming that just as demand curves slope downward, so supply curves slope upward.

The law of diminishing marginal utility may well play a significant role in this way in the determination of supply curves in conditions in which the supplies of goods are capable of being used by the suppliers themselves. But, as already pointed out, in the conditions of a

Table 5-2
Hypothetical Total and Partial Demand Schedules

Price	Total Quantity Demanded	Quantity Demanded in Market I	Quantity Demanded in Market II
\$10	100	60	40
9	125	75	50
8	160	100	60
7	200	125	75
6	250	150	100
5	325	200	125
4	400	250	150
3	500	300	200

division-of-labor economy, goods are produced in such enormous concentrations that for all practical purposes they can be viewed as possessing zero marginal utility for their producers. For example, the pin maker, shirt maker, or automobile producer who turns out tens or hundreds of thousands or even millions of units of his product, can attach marginal utility only to an insignificant fraction of his supply. On this basis, Böhm-Bawerk pointed out that it is more reasonable to regard him as attaching no marginal utility whatever to his supply, and thus as being willing to accept any price for his product that he can obtain, from zero on up, as determined by the competition of the buyers.⁵⁹ This, of course, is the basis of Böhm-Bawerk and the Austrian school regarding the supply curve as essentially a vertical line, representing a given amount that the sellers are prepared to sell, irrespective of price.⁶⁰

Nevertheless, it is possible, with some difficulty, to derive upward sloping supply curves. This can be done by conceiving of them as reflecting the competition for a given overall physical supply that arises from the existence of two or more competing demand curves that represent alternative uses for the same supply. To make this point clear, it is necessary to begin by representing the demand schedule previously shown in Table 5-1, as the summation of two lesser, partial demand schedules. These lesser, partial demand schedules can be under-

stood as the demand for a given good, such as wheat or gasoline, that exists in two distinct geographical markets, such as New York and Chicago, or the demand that exists for wheat or crude oil in two distinct employments, such as the baking of bread versus the making of crackers or the production of gasoline versus the production of heating oil. In reality, of course, the number of partial markets would be far greater, but for the sake of simplicity, we confine ourselves to the consideration of just two, which is adequate to illustrate the principle.

In Table 5-2, the column "Total Quantity Demanded" is identical with the column labeled "Quantity Demanded" in Table 5-1. However, this column is now presented as representing the sum of the quantities demanded at the various prices in Markets I and II, respectively, which are shown in the third and fourth columns of the table.

Figures 5-4 and 5-5 are derived from Table 5-2. Figure 5-4 shows the total demand curve, formed by pairing the prices shown in the first column of Table 5-2 with the quantities demanded in the second column. This results, of course, in the replication of the demand curve *DD*, previously depicted in Figure 5-1. Figure 5-4 differs from Figure 5-1 only in that a given amount of supply is now assumed to exist, namely, 200 units. This results in the drawing of a vertical supply curve *SS*, ascending from the quantity 200 on the horizontal axis. The implied equilibrium price of \$7 is shown by the

Figure 5-4
Total Demand Curve With Overall Fixed Supply

intersection of this supply curve with the demand curve DD .

The upper portion of Figure 5-5 shows the demand curves in the two partial markets, Market I and Market II, which when summed, yield the demand curve of Figure 5-4. As can be inferred from Table 5-2, in a state of equilibrium the price both in Market I and in Market II is \$7, with Market I purchasing 125 units, and Market

II, 75 units, of the total supply of 200 units. Nevertheless, it is possible to imagine one of the markets, say, Market II, purchasing varying parts of the total supply, from none of it whatever, all the way on up to the entire 200 units. The various possibilities for the division of the supply between Market II and Market I are shown in Figure 5-5 in the diagram immediately below the diagram for the

Figure 5-5
Derivation of the Upward Sloping Supply Curve from a Competing Demand Curve

Market II demand curve, that is, in the diagram labeled "Allocation of Supply Between the Markets." The allocation line is drawn as the base of an isosceles triangle, with the vertical and horizontal axes forming legs of equal length. Where the allocation line crosses the vertical axis, which is labeled Q_I , the entire supply of 200 units is shown as going to Market I and none at all as going to Market II. Where the allocation line crosses the horizontal axis, which is labeled Q_{II} , the entire supply of 200 units is shown as going to Market II and none at all to Market I. The various intermediate points on the allocation line show the various other possible combinations of supplies going to the two markets.

The diagram in the lower left-hand corner of Figure 5-5, labeled "Supply for Market I Equals Supply for Market I," has the purpose merely of showing the supply for Market I on the horizontal rather than on the vertical axis, which is where it is shown in the "Allocation of Supply Between the Markets" diagram. This is accomplished by drawing a 45 degree line through the origin. Every point on this line represents an equal distance along both axes.

Thus, on the basis of these four interrelated diagrams in Figure 5-5, it is possible to see that the greater is the supply in Market II, the smaller is the supply that remains in Market I. At the same time, corresponding to every given supply in Market I, there is a definite price in Market I, determined by the demand curve in Market I. The price paid for the supply in Market II, must match the price paid in Market I. And since the larger is the supply in Market II, the smaller is the supply that remains for Market I, the higher must be this price.

In this way, it is possible to trace out an upward sloping supply curve in Market II. We begin in the upper right-hand diagram with a supply in Market II of zero units. Reading down along the dashed line to the lower right-hand diagram, this implies a supply available for Market I of all 200 units. Reading now along the dashed line across to the lower left-hand diagram and then up to the upper left-hand diagram, it is clear that with a supply of 200 units, the price in Market I will be \$5. This is the price at which the quantity demanded in Market I equals 200 units. If the price offered in Market II is not above \$5, the implication is that Market II has no way to bid supplies away from Market I. Reading the dashed line across from the upper left-hand diagram to the upper right-hand diagram, it is clear that a price of \$5 and a supply of zero units can be considered as a point on the supply curve in Market II. This is shown in the diagram for Market II.

The remaining points on the supply curve in Market II are derived by the same method, as shown by additional dashed lines. Examination of the set of diagrams

shows that in order for a supply of 50 units to be attracted to Market II, which would leave 150 units for Market I, a price of \$6 must be paid. For only at that price is the quantity demanded in Market I reduced to 150 units, thereby releasing 50 units of supply for Market II. Similarly, examination of the diagrams shows that in order for a supply of 75 units to be attracted to Market II, leaving only 125 for Market I, a price of \$7 must be paid, since only at that price will the quantity demanded in Market I be reduced to 125 units, and 75 units be released for Market II. In the same way, a price of \$8 in Market II will attract 100 units to that market, for at a price of \$8 in Market I, the quantity demanded is reduced to 100 units and thus 100 units of the total supply are made available for Market II. A price of \$9 in Market II will attract 125 units, for at that price the quantity demanded in Market I falls to 75 units, thereby releasing 125 units of the total supply for Market II. Finally, a price of \$10 in Market II will attract 140 units, because at that price, the quantity demanded in Market I is only 60 units, thereby releasing 140 units of the total supply to Market II. Connecting these various points constitutes the drawing of the supply curve for Market II.

In effect, the supply curve in Market II is upward sloping by virtue of the fact that bringing additional supplies into Market II requires riding up the demand curve of Market I, so to speak, as the condition of outbidding Market I for progressively greater supplies. The principle is that the greater is the supply in Market II, the smaller is the supply and thus the higher is the price in Market I. It is the rising price in Market I, in the face of dwindling supplies in that market, that necessitates that larger supplies in Market II be accompanied by rising prices, in order to outcompete the buyers in Market I.

The supply schedule underlying the supply curve for Market II can be derived by means of subtracting from the total supply of 200 units available for both markets the quantities demanded at the various prices in Market I. This is done in Table 5-3.

It would be possible, of course, to apply the above procedure to derive an upward sloping supply curve for Market I from the demand curve in Market II. An upward sloping supply curve in any given partial market can be understood as resulting from the downward sloping demand curve(s) in one or more other markets that are in competition for the same overall given total supply.

Limitations of Geometrical Analysis

It should be obvious that the procedure followed for deriving an upward sloping supply curve is extremely cumbersome even when confined to just two partial markets. To apply the procedure to three partial markets would require the use of solid geometry, to show how a

Table 5-3
Derivation of an Upward Sloping Supply Schedule
from a Downward Sloping Demand Schedule

Price	Quantity Demanded in Market I	Total Supply	Quantity Supplied in Market II
\$10	60	200	140
9	75	200	125
8	100	200	100
7	125	200	75
6	150	200	50
5	200	200	0
4	250	200	0
3	300	200	0

definite supply in any given market implied various definite pairs of supplies in the other two markets. The simultaneous relationships between four or more partial markets simply cannot be shown by geometrical methods.

What is implied here is a limitation on the usefulness of supply and demand curves and of geometry in general in economic analysis. True enough, one may think in such terms as, say, fifty partial markets, each with its own demand curve, and with a larger supply in any one market causing diminished supplies in each of the remaining forty-nine partial markets and a corresponding riding up along the demand curves of those forty-nine partial markets. But at this point, even though the analysis makes reference to supply and demand curves, the references and the analysis itself have become purely verbal.

A case such as this clearly shows why the substantive relationships of economics must all be explained by an essentially verbal analysis. Geometry is capable of relating two, or at most three, elements at the same time, and can neither make qualitative distinctions among them nor consider any further aspects pertaining to them without regarding what it previously considered to be one element alone, now to be two or more elements—something which rapidly exhausts and then utterly surpasses its capacity for analysis. In contrast, a verbal analysis is capable of proceeding both in far greater breadth and in far greater depth. The relatively simple set of verbal principles concerning price determination presented in Chapters 6 through 8 of this book, will make it possible to grasp the competition that goes on for limited total supplies between any number of partial

markets. Those principles will also make it possible to understand in a far more meaningful way than is possible by the mere visualization of the intersection point of two curves the market *processes* by means of which prices are actually determined.

Contemporary economics, for the most part, is not troubled by the needless complexities and limitations created by an excessive reliance on the use of geometry, because, for all practical purposes, when it comes to price theory, its intellectual horizon is narrowly limited to that of *partial equilibrium*.⁶¹ In effect, the problems of relating what goes on in different partial markets do not arise for contemporary economics, because it is concerned only with what happens in one given market at a time. It does not derive the upward sloping supply curve it presents as typical from any consideration of competition among various partial markets, but from the operation of the law of diminishing returns.

The procedure of contemporary economics is to take the prices of the factors of production as given from the point of view of the individual business enterprise. It then assumes that as the enterprise increases its output from existing plant and equipment, it encounters diminishing returns—less output per unit of the additional factors of production—which implies that larger quantities of the additional factors of production are needed to produce equal additional units of the product. Given the prices of the factors of production, this means rising marginal costs per unit. (“Marginal costs” are the addition to total costs accompanying the production of a given additional

quantity of the product. With plant and equipment taken as fixed, they are the cost of additional labor, materials, and fuel. It is these costs which are assumed to increase per unit of additional output.) The supply curve of an industry is then assumed to consist of a summation of all such individual supply/marginal-cost curves of the constituent firms. Indeed, it is assumed to consist of a mere multiplication of the supply/marginal-cost curve of any one of the various allegedly interchangeable “representative firms” of which the industry is assumed to consist, by the number of such firms.⁶²

Confusions Between Supply and Cost

Ironically, resort to the law of diminishing returns as the basis for upward sloping supply curves turns out to be inapplicable to actual price formation in the cases in which it might appear to be most plausible—namely, agriculture and mining. These are cases in which diminishing returns occupy a prominent position and are reinforced by the closely related phenomenon of the need to resort to progressively inferior grades of land or mines in order to expand production under a given state of technology. Nevertheless, precisely in these cases, output comes in large discrete bursts, because it is seasonal and depends on the harvests, or because it can be increased or decreased only by substantial discrete increments as, for example, accompany the adding on or elimination of shifts of mine workers or the working or not working of this or that seam of mineral deposit.

In these cases, the concept of supply that is relevant to price formation is the Austro-classical concept of a fixed quantity, with price being determined by the competition of the buyers for that quantity. When the law of diminishing returns is taken as the basis of supply curves and thus of price formation in an industry, via the concept of marginal cost, the result is conceptual chaos of such magnitude that its sorting out is best left for a separate discussion.⁶³

The derivation of the upward-sloping supply curve from a rising marginal-cost schedule is only one aspect of the confusions contemporary economics suffers from in connection with the relationship between the concepts of cost of production and supply. In agriculture and mining, it confuses cases in which price is actually determined by demand and supply with determination by cost of production in the form of “marginal cost.” In manufacturing, wholesaling, and retailing, it confuses cases in which prices are actually determined in the first instance by cost of production—the *full* cost of production—with determination by demand and supply. Indeed, this is its most serious confusion in that it totally obscures the very existence of cases in which price is directly determined on the basis of cost, by making them appear to be merely another instance of price determination

falling under the general rubric of demand and supply.

Thus, contemporary economics admits the existence of cases in which the supply curve is horizontal, as in Figure 5–6 or, indeed, even downward sloping, as in Figure 5–7. In such cases, however, it continues to proceed as though prices were determined by demand and supply, merely because one can show demand curves intersecting such supply curves.

The case of horizontal supply curves is actually extremely common—probably more common than that of upward sloping supply curves. It describes the willingness and ability of sellers to supply a variable quantity at a given price. It is typical in retailing, wholesaling, manufacturing, and the service industries. For example, at the prices posted on its menu, a restaurant is prepared to serve a number of meals ranging from zero on up to the maximum number it can prepare in its kitchen. The same kind of wide-ranging variability in quantity is true of the number of haircuts a barbershop is willing to provide at the price it posts for haircuts, of the number of television sets an appliance store is willing to sell at the prices it posts, and of the quantity virtually any manufacturer is willing to sell of his product at the price he posts. One can express this phenomenon by saying simply that the supply curve is horizontal, and one can then bring the case under the formula that the price is determined by demand and supply, merely because there is a demand curve and a supply curve, and they have an intersection point.

Nevertheless, it should be obvious that the alleged

Figure 5–6
A Horizontal Supply Curve

Figure 5-7
A Downward Sloping Supply Curve

determination of price by demand and supply is totally superficial in cases of this kind. The price is actually determined by the decisions of the sellers. Their asking price, together with the demand curve, determines the quantity of the good that is demanded, and the quantity of the good demanded then determines the quantity supplied at the asking price. The critical question is, *what determines the asking prices of the sellers?* The answer, as we shall see, is consideration by the sellers of the cost of production of the item—either their own cost of production or that of competitors or potential competitors. Normally, we shall see, cost of production turns out to be the immediate determinant of the prices of manufactured or processed goods—of any goods or services whose quantity can be immediately expanded or contracted in response to changes in demand by such means as the ability temporarily to decrease or increase inventory levels and, before the inventories are depleted or accumulate unduly, to increase or decrease production from existing plant capacity.⁶⁴

Cases of this kind may appear to represent a direct contradiction of Böhm-Bawerk's proposition that prices are determined by the competition of buyers for limited supplies. For these are cases in which price is determined by the competition of sellers prepared to offer highly variable supplies.⁶⁵ Actually, there is no contradiction between the two patterns of price formation. They pertain to different situations—one to cases in which supply is a given quantity for a longer or shorter period of time, and

the other to cases in which supply can be varied in immediate response to changes in demand. Furthermore, it cannot be stressed too strongly that the bridge between the two cases has been provided by none other than Böhm-Bawerk himself, in his demonstration that determination of value and price by cost of production is itself merely a special case of the operation of the law of diminishing marginal utility.⁶⁶

At most, cost of production is a determinant of prices only in the first instance. When one investigates the nature of costs, they are always revealed as constituted by prices of factors of production. These prices are themselves determined by demand and supply, or on the basis of costs that reflect the operation of demand and supply at a further stage of remove. Ultimately, prices determined on the basis of costs are determined on the basis of demand and supply—but on the basis of demand and supply operating in broad factor markets, not the market for the individual product itself. Thus, for example, in saying that the price of new automobiles is determined by cost of production, rather than demand and supply, what is actually meant is that it is determined in the first instance by cost of production; but the wage rates, real estate prices, and many of the raw materials prices—all the prices into which the cost of production of an automobile is ultimately resolvable—are determined by demand and supply.⁶⁷

Downward sloping supply curves represent cases in which cost per unit declines as the level of production expands. The charging of lower prices in the face of higher levels of demand, which make possible operation on an expanded scale, is also clearly a case in which prices are set in the first instance on the basis of a consideration of costs of production—specifically, the ability to use declining costs to gain a decisive advantage over potential competitors by charging prices too low for their operations to be profitable, but which are not too low for one's own operations to be profitable.

The confusions of contemporary economics are such that it is largely unaware that in the cases of horizontal and downward sloping supply curves, it actually is dealing with situations in which cost of production is the immediate determinant of prices. Insofar as it is aware that these cases are different, it regards the resulting prices *as standing virtually outside the operation of normal economic law*—as representing “administered” prices, set more or less arbitrarily by one or another type of wielder of “monopoly power,” on the basis either of evil motives or at least peculiar motives. These confusions are the result of the fact that contemporary economics has lost the ability to understand determination of price by cost. It cannot deal with cases in which prices are set on the basis of a consideration of the full costs of

production, together with an allowance for earning the going rate of profit, rather than on the basis merely of marginal costs.⁶⁸

Putting aside all the confusions that have characterized their use, it is an obvious fallacy to believe that demand and supply curves can ever be derived from empirical observation. Any price and quantity demanded and supplied that one can observe is necessarily only a single point on a demand and supply curve. And, it could, conceivably, be a point on any one of a virtually infinite number of such curves! For through a given point, there is no limit to the number of lines that can be drawn—even if, as in the case of the demand curve, they must possess a negative slope.

Whenever a new price and quantity demanded and supplied are observed, it is inescapable that at least the demand curve or the supply curve has changed, and more than likely that both have changed. If neither had changed, the change in price and quantity would not have been possible. The conclusion to be drawn from this is that when different prices and quantities are observed over time, absolutely no rational basis exists for believing that what is being observed is movement along any given curve.

As previously explained, it should also be apparent on this basis that observations of rising prices associated with rising quantities demanded over time are perfectly consistent with the law of demand. The combination is explained simply by increases in the demand schedule—most likely, nowadays, as the result of an increase in the quantity of money.

The Circularity of Contemporary Economics’ Concept of Demand

Contemporary economics’ concept of demand en-

counters a problem of circularity. It explains each individual price on the basis of demand and supply. But the demand curve in each case *presupposes* all other prices in the economic system: it is constructed on the assumption of their existing and remaining unchanged. Yet if the formation of those other prices is to be explained on the basis of demand and supply curves, then the price of the good in question, which is supposedly first to be explained by demand and supply curves, must already be presupposed. Fortunately, the classical concept of demand, when taken in conjunction with the law of diminishing marginal utility, provides a way out of this circularity.

The classical concept of demand makes it possible to understand the absolute level of prices on the foundation of the quantity theory of money, which will be explained in Chapter 12. At the same time, the law of diminishing marginal utility shows that the relative prices of all goods and services that exist in some definite, given supply at any given time, are determined by their relative marginal utilities.⁶⁹ For example, the prices of wheat, crude oil, skilled and unskilled labor, the various improved and unimproved land sites, and so forth are all determined in such a way that the marginal utility attaching to the price in each case is below the utility of the marginal unit of the good in question and above the utility of a potential additional unit of the good in question. This means that the prices of these goods relative to one another reflect their relative marginal utilities. In this way, the prices of goods and services in limited supply can be explained without the error of circular reasoning. And because prices determined by cost of production are based on such prices, all prices can thus be explained without falling into the error of circular reasoning.⁷⁰

Notes

1. See Ayn Rand, “What Is Capitalism?” in *Capitalism: The Unknown Ideal*, ed. Ayn Rand (New York: The New American Library, n.d.), pp. 9–12. See also Leonard Peikoff, *Objectivism: The Philosophy of Ayn Rand* (New York: New American Library, 1992), pp. 380–384.

2. A division-of-labor, capitalist society is, of course, characterized by the existence of medium and large-sized business enterprises, in which large numbers of individual wage earners produce under the direction of businessmen and capitalists. But the formation and extent of all such enterprises is itself the product of the separate, independent thinking and acting of all the individual participants. The individual stockholders decide the extent to which it is advantageous to pool their capitals and employ other people; the individual wage earners decide the

extent to which working for such an enterprise is to their advantage compared with working on their own, as businessmen, and with working for any other such enterprise.

3. My discussion of this subject is completely indebted to the writings of von Mises and Hayek. See Ludwig von Mises, *Socialism* (New Haven: Yale University Press, 1951), pp. 111–142, 211–220, 516–521; reprint ed. (Indianapolis: Liberty Classics, 1981); idem, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 689–715. See also F. A. Hayek, *The Road to Serfdom* (Chicago: University of Chicago Press, 1944), pp. 48–50.; *Individualism and Economic Order* (Chicago: University of Chicago Press, 1948), pp. 33–56, 73–91, 119–208.

4. For a detailed discussion of the economic chaos of a socialist

state, see below, pp. 269–275, and the references cited in the preceding note of this chapter.

5. See Hedrick Smith, *The Russians* (New York: Quadrangle/New York Times Book Company, 1976), pp. 60–61.

6. The quotation is from Henry H. Villard, *Economic Development* (New York: Reinhart & Co., 1959), p. 171. Italics supplied.

7. Robert Kaiser, *Russia* (New York: Atheneum, 1976) p. 338.

8. For elaboration on the nature of economic planning under capitalism, see below, pp. 269–275, and 172–294 passim.

9. On the indivisibility of property rights and all other rights, see above, p. 23.

10. This insight, of course, is one of the greatest contributions of von Mises. See above, n. 3.

11. For elaboration of this fundamental fact, see below, pp. 682–699.

12. The truth is that to some extent the consumers' goods that are paid for in the present can be traced back to the performance of labor in the remotest periods of antiquity, indeed, to the point when man first began to use previously produced goods in the production of all goods. However, the extent to which goods of the present owe their existence to labor performed in the past diminishes in geometric progression. See below, pp. 820–824 and 852.

13. See below, p. 824. See also Eugen von Böhm-Bawerk, *Capital and Interest*, 3 vols., trans. George D. Huncke and Hans F. Sennholz (South Holland, Ill.: Libertarian Press, 1959), 2:79–118.

14. For a precise, arithmetic illustration of this point, see below, p. 360.

15. On the relationship between the accumulation of capital and the division of labor, cf. Adam Smith, *The Wealth of Nations* (London, 1776), bk. 2, Introduction; reprint of Cannan ed. (Chicago: University of Chicago Press, 2 vols. in 1, 1976).

16. Cf. Henry Hazlitt, *Time Will Run Back* (New Rochelle, N. Y.: Arlington House Publishers, 1966); originally published as *The Great Idea* (New York: Appleton-Century-Crofts, 1951) p. 155.

17. For an account of the origin and evolution of money and the contemporary monetary system, see below, pp. 506–517.

18. Cf. von Mises, *Socialism*, p. 121.

19. And, as von Mises has shown, it provides the *only* such standard. See *Socialism*, pp. 113–128, 131–135.

20. For a brilliant defense of the moral value of money and of the proposition that money *is* the root of all good, see Ayn Rand, *Atlas Shrugged* (New York: Random House, 1957), pp. 410–415.

21. Knowledge of the dependence of the division of labor on the existence of money sheds major light on the causes of the collapse of the Roman Empire, which took place following a century-long process of the destruction of money through inflation. See below, p. 950. The whole of Chapter 19 and much of Chapter 12 make clear the potential for inflation and destruction inherent in the present monetary system.

22. For a brilliant critique of the doctrine of from each according to his ability to each according to his need, see Ayn Rand, *Atlas Shrugged*, pp. 660–670.

23. On these points, see below, pp. 613–664 passim, and 580–589.

24. Cf. Ludwig von Mises, *Socialism*, pp. 319–321.

25. The passage of the Norris-La Guardia Act in 1932 eliminated the possibility of gaining federal court injunctions against mass picketing.

26. For a detailed discussion of these points, see below, pp. 420–421.

27. Of course, economic inequality can also result from differences in luck, but such differences are of relatively minor importance in comparison with the kind of differences described above and are certainly not of sufficient importance to detract in any way from the significance of these differences.

28. The discussion in this and the next several paragraphs was inspired by Henry Hazlitt's *Time Will Run Back*, pp. 88–91.

29. See *ibid.*

30. For a demonstration of how the accumulation of great fortunes is a case of one man's gain being other men's gain, see below, pp. 327–328.

31. For further explanation of why incomes that represent high rates of profit are heavily saved, see below, pp. 741–743.

32. See Milton Friedman, *A Theory of the Consumption Function* (Princeton, N. J.: Princeton University Press, 1957).

33. For elaboration of this point, see below, pp. 355–356.

34. On the feudalistic-type economic inequalities necessarily prevalent under socialism, see below, pp. 288–290.

35. See above, p. 23., for an explanation of why almost all violations of freedom entail violations of property rights. See also below, pp. 331–332, for a demonstration of the fact that the economic advantages of the feudal aristocracy vis-à-vis the serfs rested on a foundation of government power, not economic power, and were the result of a violation of property rights rather than of the use of property rights.

36. For further discussion of inheritance, see below, pp. 306–308.

37. See below, pp. 326–330 for a comprehensive demonstration of this fact.

38. *The New York Times* of January 8, 1994, reported an instance of this error with some degree of fanfare, on its first business page, as though it represented a scholarly finding.

39. For a free-market solution to the growing problems in the area of medical care, see below, pp. 378–380. See also George Reisman, *The Real Right to Medical Care Versus Socialized Medicine* (Laguna Hills, Calif.: The Jefferson School of Philosophy, Economics, and Psychology, 1994.) This pamphlet is a discussion of all aspects of the cause and cure of the current crisis in medical care.

40. See von Mises, *Human Action*, p. 333.

41. See John E. Cairnes, *Some Leading Principles of Political Economy Newly Expounded* (1874; reprint ed., Fairfield, N. J.: Augustus M. Kelley, 1967), pp. 22–29.

42. See John Stuart Mill, *Principles of Political Economy*, Ashley ed. (1909; reprint ed., Fairfield, N. J.: Augustus M. Kelley, 1976), p. 445.

43. See Böhm-Bawerk, *Capital and Interest*, 2:244–245.

44. No significance should be attached to the fact that the demand curve in Figure 5–2 is drawn as a straight line. It is drawn that way merely for the sake of convenience and is in accordance with the present-day practice of drawing such curves.

45. *Ibid.*

46. *Ibid.*

47. See *ibid.*

48. See below, pp. 219–221 and 503–506.

49. See above, pp. 53–54, and, below, pp. 566–568.

50. Indeed, it will subsequently be shown in detail that more aggregate supply itself creates equivalently more aggregate real demand precisely in this way. See below, pp. 559–564, especially Figure 13–3, on p. 561.

51. For an explanation of the law of diminishing marginal utility, see above, pp. 49–51.

52. In case the reader is wondering what would happen if the marginal utility attached to a unit of the good and to its price were the same, the answer is, nothing. The precondition of a purchase is the valuation of what is received in exchange above the valuation of what is given in exchange. Actually, as determinants of purchases, marginal utilities should be thought of in terms of ordinal rather than cardinal numbers. On this subject, see von Mises, *Human Action*, pp. 119–127.

53. Insofar as it is businessmen who buy cotton instead of wool, they will not be the parties who have the gain in marginal utility described here. Those who have the gain in marginal utility will be the consumers of cotton clothing. Precisely as a result of this fact, the consumers will favor the purchase of cotton clothing, and because of this the businessmen will buy more cotton and less wool. The change in the businessmen's purchases is thus dictated by the effects of changes in marginal utility on the consumers.

54. On the fallacies entailed in viewing a saving of expense as actually the same as an increase in income, see below, pp. 456–459.

55. To anticipate later discussion under the heading of Say's Law: given the quantity of money and volume of spending in the economic system, what determines the price level and the goods and services the aggregate demand is actually capable of purchasing at any given time is nothing other than the aggregate supply of goods and services. In this way, it is aggregate supply that determines the aggregate *real* demand. See above, n. 50 of this chapter for further reference.

56. The saving of labor and increase in employment must be

understood in terms of the overall, total quantity of labor directly or indirectly required in the production of the product. In the case of automobiles, for example, this means the labor required in the production of the iron ore and steel sheet, all the various parts and the materials required to produce them, and the equipment used at all the various stages, as well as the labor required in the auto plants. If a reduction in the overall quantity of labor required per unit of a product can be assumed to result in a corresponding reduction in the unit cost and price of the product, then a more than proportionate increase in the quantity of the product demanded results in an increase in overall employment in the production of the product.

57. See below, pp. 408–409.

58. See above, p. 9.

59. See Böhm-Bawerk, *Capital and Interest*, 2:244.

60. See above, p. 154.

61. See above, p. 7.

62. See, for example, Paul Samuelson and William Nordhaus, *Economics*, 13th ed. (New York: McGraw-Hill, 1989), pp. 540–545. See also above, pp. 7–8, for a critique of the doctrine of the representative firm.

63. See below, pp. 425–437, which are a critique of contemporary economics' doctrine of "pure and perfect competition."

64. See below, pp. 200–201.

65. This was the kind of case Ricardo considered typical. See *The Works and Correspondence of David Ricardo*, 11 vols., ed. Piero Sraffa (Cambridge: Cambridge University Press, 1952–73), 8:276–277. The essential passage from Ricardo is quoted below, on p. 414.

66. See above, p. 52, and below, pp. 414–416, for the previously referenced lengthy quotation from Böhm-Bawerk on this subject.

67. See below, p. 201.

68. See below, pp. 425–437 *passim*.

69. More correctly, insofar as they themselves are not consumers' goods, their relative prices are determined by the relative marginal utilities of their final products to the ultimate consumers.

CHAPTER 6

THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM II: THE PRICE SYSTEM AND ECONOMIC COORDINATION

PART A

UNIFORMITY PRINCIPLES

The dependence of the division of labor on the price system centers on the coordinating function of prices. The price system coordinates the various branches of the division of labor in a variety of essential respects. It keeps the various branches of industry, and thus the production of the various products, in proper balance with one another by appropriately adjusting their relative size. It does the same with respect to the relative size of the various occupations. It also achieves a harmonious balancing of the supplies of the various products produced with respect to their distribution in terms of place and time. These results are accomplished by the operation of a series of principles that I call uniformity principles, which are described and elaborated in the first four sections of this part.

1. The Uniformity-of-Profit Principle and Its Applications

The best way to begin to understand the functioning of the price system, and thus the full nature of the dependence of the division of labor on capitalism, is by understanding the following very simple and fundamental principle. Namely, *there is a tendency in a free market*

toward the establishment of a uniform rate of profit on capital invested in all the different branches of industry. In other words, there is a tendency for capital invested to yield the same percentage rate of profit whether it is invested in the steel industry, the oil industry, the shoe business, or wherever.

Profit, of course, is the difference between sales revenues and costs. The rate of profit on capital invested is the amount of profit divided by the amount of capital invested.¹

The reason for the tendency toward a uniform rate of profit on capital invested is that, other things being equal, investors naturally prefer to earn a higher rate of profit on their capital rather than a lower one. The higher is the rate of profit they earn, the larger is the amount of profit they earn per year and thus the more rapidly they can augment their wealth through saving and, at the same time, the more they can afford to consume. As a result, wherever the rate of profit is higher, and all other things are equal, investors tend to invest additional capital. And where it is lower, they tend to withdraw capital they have previously invested. The influx of additional capital in any initially more profitable industry, however, tends to reduce the rate of profit in that industry. This is because its effect is to increase the industry's production and thus to drive down the selling prices of its products. As the selling prices of its products are driven down, closer to its costs of production, the rate of profit earned by the

industry necessarily tends to fall. Conversely, the withdrawal of capital from an initially less profitable industry tends to raise the rate of profit in that industry, because less capital means less production, higher selling prices on the reduced supply, and thus a higher rate of profit on the capital that remains invested in the industry.

To illustrate this process, let us assume that initially the computer industry is unusually profitable, while the motion-picture industry is earning a very low rate of profit or incurring actual losses. In such conditions people will obviously want to invest in the computer industry and to reduce their investments in the motion-picture industry. As investment in the computer industry is stepped up, the output of computers will be expanded. In order to find buyers for the larger supply of computers, their price will have to be reduced. Thus, the price of computers will fall and, as a result, the rate of profit earned in producing them will fall. On the other hand, as capital is withdrawn from the motion-picture industry, the output of that industry will be cut, and the reduced supply it offers will be able to be sold at higher prices, thereby raising the rate of profit on the investments that remain in the industry.

In just this way, initially higher rates of profit are brought down and initially lower rates of profit are raised up. The logical stopping point is a uniform rate of profit in all the various industries.

Keeping the Various Branches of Industry in Proper Balance

This principle of the tendency of the rate of profit toward uniformity is what explains the amazing order and harmony that exists in production in a free market. It was largely the operation of this principle that Adam Smith had in mind when he employed the unfortunate metaphor that a free economy works as though it were guided by an invisible hand.

In the United States production is carried on by several million independent business enterprises, each of which is concerned with nothing but its own profit. Knowing this, and knowing nothing about economics, one might easily be led to think of such conditions as an "anarchy of production," which is how Karl Marx described them. One might easily be led to expect that because production was in the hands of a mass of independent, self-interested producers, the market would randomly be flooded with some items, while people perished from a lack of others, as a result of the discoordination of the producers. This, of course, is the image conjured up by those who advocate government "planning." It is the view of most advocates of socialism.

The uniformity-of-profit principle explains how the activities of all the separate business enterprises are

harmoniously coordinated, so that capital is not invested excessively in the production of some items while leaving the production of other items unprovided for. The operation of the uniformity-of-profit principle is what keeps the production of all the different items directly or indirectly necessary to our survival in proper balance. It counteracts and prevents mistakes leading to the relative overproduction of some things and the relative underproduction of others.

To understand this point, assume that businessmen make a mistake. They invest too much capital in producing refrigerators and not enough capital in producing television sets, say. Because of the uniformity-of-profit principle, the mistake is necessarily self-correcting and self-limiting. The reason is that the effect of the overinvestment in refrigerator production is to depress profits in the refrigerator industry, because the excessive quantity of refrigerators that can be produced can be sold only at prices that are low in relation to costs. By the same token, the effect of the underinvestment in television set production is to raise profits in the television set industry, because the deficient quantity of television sets that can be produced can be sold at prices that are high in relation to costs. The very consequence of the mistake, therefore, is to create incentives for its correction: The low profits—or losses, if the overinvestment is serious enough—of the refrigerator industry act as an incentive to the withdrawal of capital from it, while the high profits of the television set industry act as an incentive to the investment of additional capital in it.

Moreover, the consequence of the mistake is not only to create incentives for its correction, but simultaneously, to provide the means for its correction: The high profits of the television set industry are not only an incentive to investment in it, but are themselves a *source* of investment, because those high profits can themselves be plowed back into the industry. By the same token, to the extent that the refrigerator industry suffers losses or earns a rate of profit that is too low to cover the dividends its owners need to live on, its capital directly and immediately shrinks, and it is thereby made unable to continue producing on the same scale.

In this way, the mistakes made in the relative production of the various goods in a free market are self-correcting.

With good reason, the operation of profit and loss in guiding the increase and decrease in investment and production has been compared to an automatic governor on a machine or to a thermostat on a boiler. As investment and production go too far in one direction, and not far enough in another direction, the very mistake itself sets in motion counteracting forces of correction. Moreover, the greater the mistake that is made, the more powerful

are the corrective forces. For the greater the overinvestment and overproduction, the greater the losses; and the greater the underinvestment and underproduction, the greater the profits. Thus the greater the incentives and the means (or loss of means) to bring about the correction. In this way, the mistakes made in a free market are not only self-correcting, but self-limiting as well: the bigger the mistake, the harder it is to make it.

Further, in a free market, most of the mistakes that might be made in determining the relative size of the various industries and the relative production of the various goods are not made in the first place. This is because the prospect of profit or loss causes businessmen to weigh investment decisions very carefully in advance and thus to avoid mistakes as far as possible from the very beginning. In seeking to avoid losses, businessmen necessarily aim at avoiding overinvestment and overproduction. In seeking to make the highest possible profits, they necessarily aim at providing the market with those goods in whose production they do not expect other businessmen to invest enough. This last fact, incidentally, makes each businessman eager to invest sufficiently in his own industry, lest the opportunities he does not seize be seized by others instead.

In addition, the free market performs a constant process of selection with respect to the ownership of capital. Capital gravitates, as it were, to those businessmen who know best how to employ it and is taken away from those who do not know how to employ it. For those who invest in providing goods that are relatively more in demand make high profits and are thereby able to increase their capitals, and, consequently, their influence over future production; while those who invest in producing goods that are relatively less in demand earn low profits or suffer losses, and are correspondingly deprived of capital and of influence over future production. At any given time, therefore, capital in a free market is mainly in the hands of those who are best qualified to use it, as demonstrated by their past performance in investing. For this reason, too, most of the mistakes that might be made in determining the relative production of the various goods are avoided in the first place in a free market.

The Power of the Consumers to Determine the Relative Size of the Various Industries

The uniformity-of-profit principle explains not only how a free market prevents and counteracts mistakes in the relative production of the various industries, but also how the consumers in a free market have the power of positive initiative to change the course of production. All the consumers need do to cause production to shift is to change the pattern of their spending. If the consumers decide to buy more of product *A* and less of product *B*,

the production of *A* automatically becomes more profitable and that of *B* less profitable. Capital then flows to *A* and away from *B*. The production of *A* is thus expanded, and that of *B* contracted, until, once again, both *A* and *B* afford neither more nor less than the general or average rate of profit.

Of course, businessmen do not sit back and passively wait for the consumers to shift their demand. On the contrary, businessmen seek to anticipate changes in consumer demand and to adjust production accordingly. In addition, of course, they constantly seek to introduce whatever new or improved products they believe will attract consumer demand once the consumers learn of the product. Businessmen will produce anything for which they believe the consumers will pay profitable prices, and they will cease to produce anything for which the consumers are unwilling to pay profitable prices. In this sense, business is totally at the disposal of the consumers—the consumer is king, as the saying goes. In total opposition to the misguided efforts of the Marxists to contrast production for profit with “production for use,” the fact is that production for profit *is* production for use. It is production for the use of the consumers, as determined by the value judgments of the consumers themselves. It is the way production for use takes place in the context of a division-of-labor society, in which the producers produce for the needs of others, whose needs are conveyed to them by means of profit and loss.

i. The “Consumer Advocates” Versus the Consumers

It should not be difficult to see that the real advocates of the consumers—their virtual agents—are businessmen seeking profit, not the leaders of groups trying to restrict the freedom of businessmen to earn profits. Such groups, called, ironically, the “consumer movement,” seek to force businessmen to produce things the consumers do not want to buy, like seat belts and air bags in automobiles before they are sufficiently improved in comfort and reliability and reduced in cost to be attractive to many people. At the same time, the so-called consumer movement seeks to prohibit businessmen from producing things the consumers do want to buy, like breakfast cereals that are enjoyable to eat, and full-sized automobiles. As von Mises has pointed out, inasmuch as what is produced in a free economy is, in the last analysis, the result of the free choices of the consumers, the demands of the consumer advocates are comparable to efforts arbitrarily to overturn the results of a free election when one does not like the outcome. The dictatorial character of such demands should be obvious.²

Of course, whenever they can be gotten to admit that it is actually the choices of the consumers they wish to overturn, not any arbitrary decisions of businessmen, the

“consumer advocates” are almost certain to argue that they are nonetheless justified in their activities, on the grounds that they merely force the consumers to act “for their own good.” Here the “consumer advocates” lose sight of the fact that the fundamental basis of achieving the individual’s good is his guidance by his own judgment. They show absolutely no respect for the character of the consumers as rational beings, who must be persuaded by facts and logic, not compelled as though they were brutes, in the name of something allegedly more valuable than their free judgment and their dignity as rational beings.

It may well be the case that using seat belts saves lives and that if left to their own free choice, the consumers would not have used them as fast as they have been made to use them through compulsion. But what saves infinitely more lives than seat belts is the acceptance of the principle that each human being, as the possessor of reason, is valuable and competent and should be free to run his own life and pursue his own happiness. The use of any specific case as the pretext for overturning this principle opens the floodgates to unlimited destruction through the use of physical force to overrule people’s judgment and thus to prevent them from achieving their well-being or to compel them to act against their own well-being. Ayn Rand has rightly compared the use of force in the name of achieving a man’s good to an attempt to give him a picture gallery at the price of cutting out his eyes.³

ii. Consumer Safety and Pressure Group Warfare

The fact of the matter is that the consumers cannot even properly be described as irrational in refusing to use seat belts, so long as their use had (or has) the effect of making every automobile trip a physically uncomfortable experience. It cannot reasonably be claimed that the remote possibility of an accident automatically outweighs any possible physical discomfort that would have to be experienced on every trip in order to safeguard against it. Let the use of seat belts be made comfortable enough, their cost low enough, and knowledge of their benefits widespread enough, and there is no doubt that consumers will freely use them, because in such circumstances they really would benefit from their use. But when compulsion is introduced into the picture, it is an entirely different story.

Thus, even if the “consumer advocates” have succeeded in compelling the use of seat belts—by means of the threat of fines and possibly jail terms for failure to use them—what remains is the fact that the consumers have been compelled to endure what in their judgment is a chronic physical discomfort (and/or too high a cost). This cannot be justified if one values the free judgment

of the human mind and thus elementary human dignity. In sharpest contrast, under freedom, such an affront would not only have been avoided, but it might well have been avoided *while people still gained the benefit of seat belts*. When based on compulsion, the use of seat belts does not have to be comfortable and sufficiently economical—it is simply compelled, whether the consumers like it or not. When based on freedom, the use of seat belts does have to be comfortable enough and economical enough, because the consumers have to both like using them and value them above their price if they are to buy them. On a free market, these are the kind of seat belts the consumers would have to have obtained.

Only a free market can rationally decide such questions as whether or not seat belts, and now air bags, should be installed in automobiles. In a free market, if air bags, for example, represented a major advance in automobile safety, one of the consequences would be that their presence would so reduce the costs of insurance companies in the settlement of injury claims that the insurance companies would be in a position significantly to reduce the premiums of whoever owned a car which had one. This saving in insurance premiums, coupled with the personal benefits of reduced likelihood of serious injury, would then be weighed by the consumers against the cost of having air bags installed, or the additional cost of buying an automobile that came with an air bag in comparison with one that came without an air bag. The greater the reduction in physical injuries, and the financial costs associated with them, that air bags achieved, and the lower the cost of installing air bags, the greater would be the demand for air bags. Depending on these data, the potential quantity of air bags demanded would exist on a continuum ranging from none at all, in the event the advantages were deemed insufficient by everyone relative to the additional cost, down through high-cost luxury add-on or option, down through widely chosen add-on or option, down through standard feature on some or most new models, down through standard feature on all new models.

Things are very different in a hampered market economy, such as today’s so-called mixed economy, with its pressure-group warfare. In such conditions, each pressure group seeks to violate the rights of others for its own benefit, either for its own aggrandizement or in order to make good the depredations of others that have been inflicted on it. Thus, the automobile insurance industry—itsself made to bear the skyrocketing medical costs caused by government intervention into health care (insofar as it must pay the medical bills of the victims of automobile accidents), bled white by jury awards based on the notion that any large corporation is fair game for anything, and the victim of government interference to the point of

being rendered incapable of controlling the automobile repair costs it must pay—forms into a pressure group and joins the “consumer advocates” in demanding that the automobile industry install air bags. It acts in the hope that the reduction it expects to have in its own costs will serve as a reprieve. As cover, it waves the banner of consumer safety, while making no mention of the higher prices that consumers will have to pay for automobiles. Ironically, at the same time, on the basis of their own accumulated grievances, automobile owners join in demands for rate rollbacks for the insurance companies.

And while this goes on, the “consumer advocates” lead an ignorant public to believe that the costs imposed on the automobile industry in the name of safety, fuel economy, pollution control, and whatever are somehow just at the expense of the automobile companies and have nothing whatever to do with raising the cost of production and price of automobiles. The fact is, of course, that such legislation has already added several hundred dollars to the cost of the average new automobile that is sold in the United States. The paradoxical effect of this has actually been to work to *reduce* automobile safety! To the extent that new automobiles are made more expensive than they need to be, people are compelled to operate their cars longer. Since older cars as a rule are not as safe as new cars, this means that people are forced to drive in automobiles that are not as safe as they would be in the absence of automobile safety legislation and allied legislation. Thus, the introduction of physical force into the issue of automobile safety (and anywhere else in the market) actually has the perverse effect of operating to reduce safety.⁴

The Impetus to Continuous Economic Progress

The uniformity-of-profit principle explains how the profit motive acts to make production steadily increase in a free market. It explains how the profit motive becomes an agent of continuous economic progress.

In order to earn a rate of profit that is above average, it is necessary for businessmen to anticipate changes in consumer demand ahead of their rivals, to introduce new and/or improved products ahead of their rivals, or to cut the costs of production ahead of their rivals. I say, “ahead of their rivals,” because as soon as any innovation becomes general, then, in accordance with the uniformity-of-profit principle, no special profit can be made from it. For example, the first firms that produced shoes by machinery rather than by hand, or put zippers in clothing, or found a way to sell a cigar for ten cents, or whichever, were able to make above-average rates of profit by doing so. But once such things became general, no special profit could any longer be made from them. They became the ordinary standard of the industry and were taken for

granted. Sooner or later, virtually every innovation does become general. This implies that for any firm to continue to earn an above-average rate of profit, it must *repeatedly* outdistance its rivals; it must work as an agent of continuous economic progress.

Perhaps one of the most dramatic examples of this is provided by the career of the first Henry Ford. When the Ford Motor Company began, in the early part of the twentieth century, the automobile was a rich man’s toy. Extremely primitive models by our standards were selling for about \$10,000—in the very valuable money of the time.⁵ Henry Ford began to find ways to improve the quality of automobiles and at the same time cut the costs of their production. But it was not possible for Ford to make a single improvement or a single cost reduction and stop there, because it was not long before those innovations were generally adopted in the industry and, indeed, superseded. Had Ford stood pat, it would not have been long before his once profitable business was destroyed by the competition. In order for Ford to go on making a high rate of profit, he had to continuously introduce improvements and reduce costs ahead of his rivals.

The same is true in principle, in a free market, of any individual or firm that earns an above-average rate of profit over an extended period of time. What was good enough once to make a high rate of profit, ceases to be good enough as soon as enough others are able to do the same thing. In order to go on earning an above-average rate of profit, one must continue to stay ahead of the competition. By the same token, any business that stands pat is necessarily finished in a free economy, no matter how great its past successes. For the technological advances of any given time are further and further surpassed as time goes on. Think how absurd it would be in virtually any industry to try to make money today by producing with the most advanced, most profitable technology of 1900, 1940, or even 1980, and not bothering to adapt to the changes that have taken place since then.

It is necessary to explain in more detail how the competitive quest for an above-average rate of profit expands the total of production.

If a firm is a leader in the improvement of production, it expands its sales revenues and profits at the expense of the sales revenues and profits of other firms that are less quick to improve. This is because it has something better or equally good but less expensive to offer than they do; and so buyers shift their purchases to it, thereby enlarging its sales revenues and profits and diminishing the sales revenues and profits of other firms.

(It is important to realize that this same result—the innovative firm’s gain in sales revenues and profits accompanied by a decline in the sales revenues and profits

of others, who are less innovative—occurs even in the exceptional case in which a business cuts its costs of production and yet keeps its selling price absolutely unchanged. In this case, it does not attract sales revenues from other sellers in the same industry, but it almost certainly attracts sales revenues and profits from sellers in different industries. Because to the extent that it saves, and reinvests its extra profit anywhere in the economic system, it will bring about an increase in production. This new production in some other line of business will take sales revenues and profits away from whichever sellers buyers now abandon in order to be able to purchase this new production. For example, imagine that a maker of razor blades, say, finds a way to cut his costs, and yet chooses not to cut his selling price at all. He will not reduce the sales revenues and profits of other razor blade manufacturers, but to the extent that he saves, and invests his profit in the production of some other product—whether it is an after-shave lotion, chocolate bars, or anything—he will increase the supply of that product and take sales revenues and profits away from somewhere else in the economic system, because to buy this additional product of his, people will have to restrict their expenditures for other things.)

Now the combination of an innovator's higher profits and others' lower profits or outright losses is what then impels these others to improve their production, too. These others may simply want to cash in on the high profits of the innovator and so duplicate his innovation for that reason. Or they may be in the position of *having* to duplicate his innovation in order merely to stay in business.

It cannot be stressed too strongly that under the freedom of competition, innovations must be adopted not only to make exceptional profits, but to be able to make *any profits whatever*. They must be adopted merely to be able to remain in business at all. This is true because sooner or later, as the result of the freedom of competition, virtually all cost cuts are translated into price cuts, and whoever does not produce with the lower-cost method cannot cover his costs. Even in our present-day, highly inflationary environment, in which wages rise every year and prices hardly ever fall, it is necessary for all producers to adopt cost-cutting improvements. They must adopt them in order not to have to raise prices in full proportion to the increase in wages and so be in the untenable position of requiring price increases greater than their competitors' in order to stay in business.

As indicated, there is probably no business in the United States today that would still be in business had it not adopted major innovations over the last generation and probably even over the last decade. It is not possible for a business to sell at the same prices as others and yet

produce at substantially higher costs—not when its selling prices are governed by their lower costs. Nor is it possible for a business to sell a substantially poorer product than others at the same price they are asking for a better product. The penalty for falling too far behind either in efficiency or in quality of product is going out of business. The only way to avoid this penalty is by adopting the innovations before it is too late.

The fact that sooner or later competitors do adopt innovations not only enables them to increase their own profitability, or at least to restore it and thus to survive (which of these it is depends on how much sooner or later they adopt them), but it also takes away the special profits of the innovators. The fact that the special profits of innovating do tend to disappear, because competitors catch up, is what necessitates that everyone who wants to go on making an exceptional rate of profit over an extended period of time introduce repeated innovations. If he is to prevent the loss of all his special profits to competitors who are catching up, he must make fresh advances over them. In this way, the combination of the profit motive and the freedom of competition leads successful producers to seek continuous improvements. That is the only way they can sustain an exceptional rate of profit; they cannot rest content merely with their past successes.

In connection with the freedom of competition, it should be realized, moreover, that the ranks of businessmen are open to everyone, including penniless newcomers. Those who have a valuable idea, but lack the funds to implement it themselves, can offer a partnership to others who do have capital; and further capital can be borrowed. In a capitalist society, there is an enormously large number of possible sources of financing for any new idea. It is equal to the number of individuals or combinations of individuals who possess the amount of capital required. For example, if a million dollars is the sum required, there are as many potential sources of financing as there are individuals or combinations of individuals who possess a million dollars or more.

This situation guarantees that every new idea has many possible chances for being implemented. If the innovator does not possess the necessary capital himself, he can turn to as many separate sources of financing as there are individuals or groups who do possess the necessary capital. It is not necessary for him to convince everyone, a majority, or even a significant-sized minority of his fellow citizens that his idea is valuable before he can put it into practice. If he owns the necessary capital himself, he can go ahead without convincing any other person at all. If he does not own the necessary capital himself, then he needs to convince only a minority consisting of possibly just one other person, and in no case

of more than a relative handful of people who in combination possess the necessary capital.

The importance of this fact cannot be overestimated. Not only are new ideas always the product of individual minds, known at first to just one individual member of the whole human race, but also, no matter how sound or important they are, their value is often not recognized for a considerable time by the overwhelming majority of other people. To confirm this fact, one has only to recall the difficulties even of such giants of progress as Columbus, Pasteur, Edison, Ford, the Wright brothers, and Goddard in obtaining recognition and support for their profoundly important innovations. Columbus had to spend years attempting to raise funds for his voyage, and was very lucky finally to succeed in doing so. Pasteur's theory that germs cause diseases was denounced by the French Academy of Sciences as a fraud. Edison's claim that he could produce electric light was denied by most of the physicists of his day. Ford and the Wright brothers were widely regarded as cranks. Goddard's ideas on rocketry and space flight were dismissed with contempt by such prominent publications as *The New York Times*. In the absence of a wide range of chances for new ideas being tried, the great majority of valuable innovations are unlikely to be tried, and, in the face of that prospect, unlikely even to be arrived at in the first place. In order for new ideas to flourish, it is essential that a sufficient number of opportunities for their implementation exist so that innovators can above all find ways around the prevailing "mainstream" views—that is, the views of the then current "experts." As von Mises often pointed out, the "experts" are always experts merely on the state of knowledge up to their time, never on the subject of new knowledge, which in the nature of the case has not yet entered the "mainstream" and is often at odds with the "mainstream."

Thus, in connection with the operation of the uniformity-of-profit principle, a capitalist society provides the incentive of profit to introduce continuous innovations and the incentive of avoiding losses to adopt the innovations of competitors. At the same time, it opens the possibility of introducing innovations to everyone in the entire society and provides an enormous number of possible sources of financing for innovations. It is impossible to imagine an economic system that could be more conducive to economic progress.

As for the translation of this process of innovation into terms of physical increases in production, it is probably self-evident that the introduction of new and/or improved products constitutes an increase in production or is a source of an increase in production. One has only to think of such cases as the automobile replacing the horse and buggy, or the automobile with the self-starter replacing

the hand-cranked automobile, or such cases as the tractor bringing about a vast increase in the production of agricultural products, or the electric motor bringing about a vast increase in the production of all kinds of manufactured goods. It may be less obvious, however, how the day-by-day attention of businessmen to costs, and their constant efforts to reduce the costs of production, are an equally important source of the increase in production. Still less obvious is the role in increasing production that is played by correct anticipations of changes in consumer demand. Therefore, let us briefly consider the contribution of these factors to increasing production.

Reducing the costs of production means, for the most part, that one finds a way to produce the same amount of a good with less labor. This acts to increase production because it makes labor available to produce more of this good or more of other goods, somewhere else in the economic system. The saving of labor is clearest in the case in which the businessman achieves the cost reduction by employing labor-saving machinery. But even if the cost reduction is achieved by finding a way to use less of some material or a less costly material, labor will also be saved. If less of a material is required, less labor is required to produce the smaller quantity of the material. If a less costly material is required, it is probable that labor will be saved, since it is probable that the less costly material is less costly because less labor is required to produce it. To this extent, then, saving costs means saving labor and, therefore, making the means available for increasing production.

Even if a saving in the quantity of labor is not involved in a cost reduction, the ability to produce something with a less costly material, or with less costly labor for that matter—say, unskilled labor in place of skilled labor—still brings about a net increase in total production. What happens in these cases is that the more costly material or labor is released to expand the production of something else which is comparatively important, while the less costly material or labor that replaces it is withdrawn from the production of something else which is comparatively unimportant.

The principle here is perhaps best illustrated by the case of employing nurses and other aides for many of the tasks that would otherwise have to be performed by doctors. What is gained is the added work that can only be performed by doctors and which otherwise would have been impossible for lack of availability of doctors' time. What is lost is only the work that the nurses or whoever might have performed as secretaries, bookkeepers, or whatever. Every substitution of less costly labor for more costly labor is comparable to this case in its effect. The same applies to the substitution of less costly for more costly materials. In this way, a net economic

gain, equivalent to an increase in production, takes place, because the production of something more important, that is, something with higher marginal utility, is increased at the expense of the production of something less important, that is, something with lower marginal utility. As far as labor goes, the ability to substitute unskilled for skilled labor and achieve equal results can also be viewed as the equivalent of increasing the intelligence and ability of workers, which in the very nature of the case must increase production.⁶

The correct anticipation of changes in consumer demand is also a necessary part of the process of increasing production. To understand this point, it must be realized that increases in production are one of the most important causes of wide-ranging changes in the pattern of consumer spending. For example, the steady improvements in agriculture and the consequent drop in the proportion of people's income that has had to be tied up in buying food has made possible a continuously growing demand for the whole range of industrial goods. Similarly, the introduction and development of the automobile brought about far-reaching shifts in demand: it made possible the development of the suburbs and a whole host of new businesses from gas stations to motels; expanded the demand for other businesses, such as ski resorts; reduced the demand for passenger railroads and horses; and virtually destroyed the businesses of buggy-making and blacksmithing. Every improvement in production exercises a similar, if less dramatic, effect on the demand for other goods.

In order for these shifts in demand to be accompanied by corresponding shifts in production, it is necessary for wide-ranging changes in the investment of capital to occur. Thus, to continue with the examples of agriculture and the automobile, capital had to be diverted from agriculture to industry, from cities to suburbs, from railroads, horsebreeding, buggy-making, and blacksmithing, to automaking, gas stations, motels, and ski resorts. To the extent that the appropriate shifts of capital did not occur, or occurred with undue delay, the benefit from the improvement in production was lost. For example, to the extent that capital was not shifted out of farming rapidly enough—as a result of government farm subsidies or the inertia of many farmers—the effect of the improvements in agriculture was limited to a relatively unwanted increase in agricultural production and correspondingly less of an increase in much more desired industrial production. Similarly, to the extent that capital would not have been shifted rapidly enough out of buggy-making and horsebreeding, the benefits from the automobile would have been held down: capital would have been wasted in buggy-making and horsebreeding which could have been employed with infinitely greater benefit in any

of the new or expanding industries brought about by the automobile. In all such cases, to fail to make the appropriate shifts of capital is to lose some or all of the benefit of the improvement in production. For this reason the correct anticipation of changes in consumer demand is an integral part of the process of increasing production.

I have established that the effect of the quest for an above-average rate of profit in the face of the operation of the uniformity-of-profit principle is to bring about the steady improvement and enlargement of production. The inescapable implication of this fact is a powerful tendency for prices to fall from year to year. It is necessary to reconcile this implication with the fact that based on the experience of almost everyone now living the reality appears to be that prices rise virtually every year.

The fall in prices that the profit motive has actually achieved can be clearly seen if prices are calculated not in terms of depreciating paper money, but in terms of *the amount of labor that the average worker must perform in order to earn the means of buying any given quantity of goods*. Today, the average worker performs perhaps forty hours of labor in a week and is able to obtain the goods that constitute his present standard of living. As we look back in time, however, we see that the hours of work that had to be performed were greater, and the goods constituting the average worker's standard of living were less. Thus, as time has gone on, and the average worker has come to receive more and more while working less and less, the quantity of goods he can obtain for each hour of his labor has increased. To say the same thing in different words, *the amount of labor he must perform in order to obtain a unit of goods has steadily decreased*. In this sense, prices—calculated in terms of the quantities of labor that must be performed in order to buy goods—actually have fallen steadily as the result of the operation of the profit motive.

The fact that in terms of paper money, prices have risen is the result of the fact that while prices of goods really do tend to fall because of the operation of the profit motive, the value of the paper money tends to fall still faster. When falling prices are expressed in a standard that itself falls even more rapidly (which is the case with paper money), they have the appearance of having risen. The following illustration will make this point obvious. In the early 1970s a primitive four-function pocket calculator sold for about \$400. At the same time, a fairly primitive video tape recorder sold for about \$2,400. Thus, at that time, it took 6 pocket calculators to represent the price of one video tape recorder. Today, the price of a much improved video tape recorder is about \$400—which certainly represents a radical drop. But today, the price of a comparable pocket calculator is only about

\$10. Thus, today, it takes 40 pocket calculators to equal the price of a video tape recorder instead of only 6. When the lower price of the video tape recorder is expressed in terms of pocket calculators, it appears to have risen instead of fallen, because the price of the pocket calculator has fallen so much more.

Exactly this principle applies to the rise in prices in terms of paper money. While the profit motive operates to reduce the prices of the mass of commodities and does in fact succeed in reducing them when expressed in any kind of reasonably fixed standard of value, the value of paper money falls even more rapidly and so gives the appearance that things have become more expensive instead of less expensive.

This result can be further understood if we realize that paper money is actually among the cheapest goods in the world to produce in the first place. It starts out with a virtually zero cost of production. If its production were open to the freedom of competition, so that anyone in possession of the appropriate paper and printing plates was allowed to manufacture it, its value would quickly be driven down to the value of goods with a comparable cost of production, such as pieces of note paper and pins. Indeed, its value would even be less, because it would not have the actual physical utility of such goods, and the need to carry vast quantities of it to buy other goods would destroy its usefulness as money. In other words, under the freedom of competition, the profit motive would soon make paper money absolutely worthless. All other goods would be worth an infinite quantity of it.

The value of paper money is not destroyed this quickly, because its creation is a monopoly privilege of the government. But even so, as we shall see, the government has powerful incentives to increase the quantity of paper money at a substantially more rapid rate than the scientists, inventors, businessmen, and savers and investors are able to increase the supply of goods.⁷ The result is that while the productive work of these most intelligent and ambitious members of society may succeed in an average year in increasing the supply and thus tending to reduce the prices of goods by, say, three, four, five percent, or whatever, the government is easily able to outstrip their performance and increase the quantity of money and volume of spending in the economic system by a larger amount, with the result that prices rise instead of fall.

To summarize the discussion of the price system thus far: The desire of businessmen to earn profits and avoid losses, and to earn higher profits in preference to lower profits, brings about a tendency toward a uniform rate of profit on capital invested in all the different branches of industry. The operation of this tendency counteracts,

delimits, and largely prevents mistakes from being made in the relative production of the various goods. Because of it, consumers have the power of positive initiative to shift the course of production simply by changing the pattern of their spending; because of it, businessmen are made to act virtually as the consumers' agents. The operation of the tendency toward a uniform rate of profit requires that high profits be made by continuously introducing productive innovations in advance of competitors. These innovations are the base of a continuous increase in production, whether they take the form of new and improved products, reduced costs of production, or correct anticipations of changes in consumer demand. As such, they operate continuously to raise the average standard of living. They steadily enlarge and improve the goods available while reducing not only the amount of work that must be performed in order to produce any given quantity of goods but also the amount of work that must be performed in order to buy any given quantity of goods. In other words, they make possible progressively improved products at prices corresponding to progressively falling real costs of production.

On the basis of the foregoing, we must conclude that the profit motive and the price system of capitalism have been responsible for virtually all of the economic progress of the last two hundred years or more. They have ensured the maximum possible effort to introduce innovations and to extend their application as rapidly as possible, with the result that in comparatively short periods of time revolutionary improvements have become commonplace. Because of this and because of the rapid adaptation they assure to all changes in economic conditions, they have rendered every crisis, from natural disasters, to wars, to absurd acts of government, a merely temporary setback in a steady climb to greater prosperity.

Profits and the Repeal of Price Controls

What we have learned about the free market can be applied to a number of cases in which the free market does not or for a time did not exist in our country. A brief consideration of these cases will both illustrate the principle of the tendency of the rate of profit toward uniformity and provide a demonstration of the value to be gained by extending the free market.

Consider the case of government farm subsidies. Let us imagine that the government stopped buying up farm products to be stored or given away, and at the same time reduced taxes by the amount of money it saved in abolishing the farm subsidy program.

The effect would be a drop in the demand for farm products. But since the taxpayers would now have the money previously used to pay the subsidies, there would be a rise in the demand for a host of other products—

products which the taxpayers judged would satisfy the most important of their needs or wants which previously had had to go unsatisfied, such as an extra room added on to a house, a newer or better car, extra education, and so on, depending on the needs and desires of the various individuals concerned. The immediate effect of this shift of demand would be to depress prices and profits in farming and to raise them in these various other industries. The further consequence would be a withdrawal of capital and labor from farming and their transfer to the production of these other goods.

The movement of capital and labor out of farming would take place until the rate of profit in farming was raised back up to the general level, and the rate of profit earned on the various goods in additional demand by the taxpayers was brought down to the general level. Until this result was achieved, incentives would exist for a further movement of capital and labor out of farming and into these other fields. When the process was finally completed, therefore, the rate of profit earned in farming would be on a par with the rate of profit earned everywhere else. In accordance with the uniformity-of-profit principle, it would simply not be possible for the rate of profit in farming to be permanently depressed.

It follows from this analysis that in the long run those who remained in agriculture would tend to earn, on average, the same level of income they had earned before the repeal of the subsidies. Even the incomes of ex-farmers would, on average, come to be on a level comparable to what they had been initially. This would be the case as soon as the former farmers acquired industrial skills on a level comparable to those they had possessed in agriculture and so could take appropriate advantage of the new employment opportunities created by the expansion in the demand for industrial goods. The one permanent difference that would now exist and which would be of benefit to everyone, farmers and ex-farmers included, would be that the taxation of everyone's income would be smaller and everyone would be enabled to buy more of the goods he himself desired. Instead of everyone being forced to spend a part of his income, through the government, for the purchase of farm products to be uselessly stored or given away, he would be able to spend that part of his income for industrial goods of value and importance to his life. And those goods would be produced by the capital and labor previously employed in producing the farm products.

In sharpest contrast to the beneficial effects the uniformity-of-profit principle brings to the abolition of farm subsidies, are the further harmful effects it leads to if farm subsidies are retained. Insofar as the subsidized prices are above the costs of producing additional agricultural

output by more than is necessary to provide the going rate of profit, the incentive is created to increase production. The incentive is created to increase production all the way to the point that any further increase would have to be carried out under conditions of such diminishing returns and need to resort to land of inferior quality, that higher costs of production would finally offset the receipt of the artificially higher farm product prices and bring the rate of profit in agriculture down to the general level in this way. To reach this point, the government would have to purchase and store truly immense quantities of agricultural commodities. It would not only run out of grain elevators, as it did, but also probably run out of caves and the holds of mothballed ships, to which it has actually turned for use as supplementary storage facilities. And, not to be overlooked, its budget would be thrown substantially further out of balance.

To avoid these consequences, the government is led to seek ways to limit the increase in production its policy of farm subsidies makes profitable. Thus, it restricts the number of acres that can be planted. It may require that the growers have a special license in order to grow a crop. To a large extent the effect of this policy is to allow inefficient, high-cost producers to go on producing while prohibiting production by more efficient, low-cost producers. In a free market, the low-cost producers would expand production, drive the price down, and force the high-cost producers out of business. But this cannot happen when the price is prohibited from falling and the government restricts production.⁸ This added policy of restricting production, of course, represents a blatant infringement of the right of people to use their own property as they see fit. And it has even taken such bizarre forms as imposing fines on farmers for growing food to feed to their own animals. The rationale for this outrage is that such food production makes it possible for the farmers in question to avoid buying feed and thus with the same feed production reaching the market imposes on the government the need to make additional purchases to maintain the price of crops used as feed. Thus individual liberty is sacrificed in order to hold down government expenditures which are absurd in the first place. In effect, the government begins by playing the role of a fool and ends by becoming a tyrant.

As a result of farm subsidies, until very recently a major portion of agricultural output was worse than wasted—it was used to sustain Communist regimes around the world through being given away to them for nothing under such programs as “Food for Peace,” or in exchange for funds provided to the Communist regimes by private banks under loans whose repayment was guaranteed by the U.S. government. In sustaining these regimes, which would otherwise have fallen many years

ago from a lack of food supplies caused by the inherent nature of socialism, the farm subsidy program perpetuated the need for large-scale defense spending, in order to be able to provide security against the permanent policy of aggression of such regimes. It thereby operated to multiply the burden of taxation far beyond its own, direct cost.

A related consequence of the existence of agricultural surpluses which would otherwise rot, and which the government's restrictions on production have served merely to diminish, not eliminate, has been the encouragement of public dependency and unemployment in the United States. These are results of the food stamp program, which provides large numbers of American citizens with the ability to obtain free food, and thus acts as a major public welfare program, enabling many people to live without working.

I chose the example of farm subsidies mainly to illustrate how the free market reacts when the profitability of an industry is initially rendered low. Farm subsidies, however, represent a form of price controls different from the kind we shall predominantly be concerned with in the first half of this book. Farm subsidies are a way the government achieves artificially high prices. They are an illustration of legal minimum prices—that is, prices below which the government prevents the producers from selling. They are comparable in their effects to minimum-wage legislation. They cause unsaleable surpluses—which, in the case of labor, means unemployment. We will deal with such price controls further and at length in the second half of this book, in the discussion of unemployment and depressions. The kind of price controls that we want to focus on first, because they are most directly relevant to the subject of the dependence of the division of labor on capitalism, are controls designed to keep prices artificially low—that is, legal maximum prices or ceiling prices, namely, prices above which one is not allowed to sell.

Thus let us take as a second major illustration of the effects of the repeal of price controls, the consequences that would follow if rent controls were repealed.

To simplify this discussion, let us assume that the entire supply of rental housing in a given locality has been under controls. In this case, the first effect of the repeal of controls would simply be a jump in all rents. As a result of the jump, however, rental housing would again become profitable—in fact, as a result of previously inadequate building due to rent controls, extremely profitable. However, it is impossible that the rental housing industry should be permanently more profitable than other industries. The high rate of profit would be the incentive, and would itself provide much of the means,

for expanded investment in the rental housing industry. There would be a building boom in rental housing. As a result, the supply of rental housing would be stepped up and the rents and the profitability of rental housing would begin to fall and would go on falling until the rate of profit in rental housing was no higher than the rate of profit in industry generally. The long-run effect of the repeal of rent controls, therefore, would simply be an increase in the supply of rental housing. Rents themselves in the long run would be no higher than corresponded to the costs of constructing and operating apartment houses, with profits only enough to make the industry competitive, by providing the going or average rate of profit.⁹

Exactly the same effects would follow the repeal of price controls on crude oil, natural gas, or any other good. There would be a temporary surge in price and profit, followed by expanded production and a reduction in price and profit to the point where the price corresponded to the good's production cost and allowed only enough profit to make the good's production competitive. The repeal of the price controls on domestically produced oil and oil products in the United States in 1981 provides an excellent illustration of this proposition. After a temporary surge in its profitability, followed by a major expansion in domestic production and fall in the price of oil and oil products, the American oil industry ceased to be extraordinarily profitable.

Of course, it should not be forgotten that once a price control is repealed, the dynamic effects of the uniformity-of-profit principle take over. As we have seen, if someone wants to make an above-average rate of profit on a free market, he must strive to reduce his costs of production and improve the quality of his products, and repeatedly succeed in doing this ahead of his rivals. This means that in the absence of controls, costs and prices tend steadily to *fall*—if not in terms of a depreciating paper money, then nevertheless in terms of the time people must spend to earn the money to buy goods. Once controls are repealed and a free market established, the free competitive quest for high profits causes prices to fall further and further below the point at which they were controlled, while the quality of goods rises higher and higher.

It should be obvious that the repeal of rent controls would act to end New York City's housing shortage and make possible an enormous improvement in the quantity and quality of housing for the average person in New York City, and continuing improvements thereafter. It should be equally obvious that the repeal of price controls on crude oil and on natural gas, if not sabotaged by such measures as the government's physically closing off the sources of an expanded supply of energy, act to set the stage for growing supplies of these goods and thus

for a return to America's traditional abundance, indeed, growing abundance, of energy supplies.

In sum, it should already be clear, even at this stage of our knowledge, that the problems we have experienced in these areas have been the result of government controls and that the solution lies with the extension of economic freedom and thus, among other things, of the ability of the profit motive and the price system to operate to achieve their benevolent consequences. More broadly, the solution lies with the intensification of the capitalist elements that have traditionally characterized the economic system of the United States, and which have been increasingly restricted.

Of course, the ability of the profit motive and the price system, and other essential elements of capitalism, such as saving and capital accumulation, to achieve continuous economic progress, should not be thought to be hindered in any fundamental way by a possible lack of natural resources. Nor should such economic progress be thought to be dangerous or undesirable by virtue of "harming the environment." I have already demonstrated in Chapter 3 how capitalism operates continuously to increase the supply of economically useable natural resources along with the supply of products. In the same place, I have also shown how the inherent nature of production is to make the chemical elements provided by nature, and which constitute the totality of the physical world, stand in an improved relationship to man—that is, to improve his environment.¹⁰

The Effect of Business Tax Exemptions and Their Elimination

The uniformity-of-profit principle sheds light on the effect of business tax exemptions and their elimination. For example, for many years prior to 1975, the U.S. oil industry, along with other extractive industries, was able to deduct from its taxable income a depletion allowance based on the value of the oil it extracted, and thus to reduce its overall effective rate of taxation. The effect of the depletion allowance was not to make the oil industry permanently more profitable than other industries, however.

It is true that the initial effect of such a tax advantage is to raise an industry's after-tax rate of profit relative to that of other industries. But the higher after-tax rate of profit then results in the attraction of additional capital to the industry, and itself provides such additional capital, with the result that the industry's rate of profit falls back toward the general, average after-tax level. The effect is that the industry is larger, its production is greater, and the price of its product is lower. It does not permanently earn a higher rate of profit.

This principle applies even if the industry is totally tax

exempt. Then the effect is simply that the industry's expansion is carried that much further, but not that its rate of profit remains permanently above the going or average rate. The total exemption from the federal income tax of bonds issued by state and local governments provides an excellent illustration of the principle. Because of their tax exemption, these bonds are purchased to the point that the rate of return they afford is on a par with the after-tax rate of return of bonds that are fully subject to the federal income tax.

By the same token, of course, repeal of a tax exemption, once it has been incorporated into the pattern of investment, is tantamount to a reduction in an industry's rate of profit. If its effect is to reduce the industry's rate of profit below the general rate, then the consequence will be a withdrawal of capital and a reduction in the size of the industry, until the smaller industry that remains can once again earn the going rate of profit—by charging a higher price for its product. (If the rate of profit of the industry is not pushed below the going or average rate, because of the presence of some factor such as an increase in the demand for the industry's product, the effect will be that the industry will grow less than it otherwise would have, and the price of its product will not fall to the same extent that it otherwise would have.)

In the 1970s, in the midst of a widely proclaimed "energy crisis," the U.S. government, in addition to imposing price controls on oil, acted to further restrict oil company profits, and thus oil industry investment, by punitively increasing their rate of taxation precisely by first reducing and then totally abolishing the customary depletion allowance on crude oil. The effect was a further blow to domestic oil production.

Additional Bases for the Uniformity-of-Profit Principle

Before leaving the uniformity-of-profit principle, it must be pointed out that in addition to changes in the selling prices of products resulting from changes in the amount of capital invested in an industry, other factors also operate to establish a uniform rate of profit among the different branches of production. One of these has already been indicated in the discussion of the effects of repealing or maintaining farm subsidies. There it was pointed out that as agricultural output is increased, unit costs rise as the result of the operation of the law of diminishing returns and the need to resort to land of inferior quality. The same factors operate on unit costs in the case of mining. And obviously they operate in reverse when it is a question of reducing the production of agricultural commodities or minerals. Thus, in cases of this kind, the investment of additional capital operates to reduce the rate of profit by virtue of bringing about a

combination of lower selling prices and higher unit costs of production, not simply lower selling prices alone. By the same token, the withdrawal of capital in such cases operates to raise the rate of profit by virtue of a bringing about a combination of higher selling prices and lower unit costs of production, not simply higher selling prices alone.

A second, similar factor, which is of relevance throughout the economic system, is a possible rise or fall in the prices of the factors of production used in an industry, as the capital invested in the industry, and thus its level of output, increases or decreases. As later discussion will show, factors of production such as labor and many raw materials exist at any given time in a given supply. The prices of such factors of production are determined by the combination of their given supply and the prevailing demand.¹¹ Thus insofar as changes in capital investment change the relationship between the demand for such factors of production and their supply, they change the prices of such factors of production.

Thus, for example, if the demand for one product rises and the demand for another product falls, and if the labor or raw materials used in the production of the products cannot be transferred from the one to the other, then changes in the prices of these factors of production will occur. For example, if the demand for a product made of iron rises and the demand for a product made of cotton falls, no part of the supply of cotton can be used to meet the additional demand that will result for iron ore. Nor can the land that produces cotton be used in the production of additional iron ore. As a result, the effect will be a rise in the price of iron and a fall in the price of cotton. Similarly, if the demand for a product requiring one type of labor skill rises while the demand for a product requiring a different type of labor skill falls, the result will be a rise in the wage rate of the one kind of labor and a fall in the wage rate of the other kind of labor.

In all such cases, the industry whose product is in greater demand and whose rate of profit has been elevated above the average, will, as before, experience an influx of capital investment. In these circumstances, the effect of the additional capital investment will be not only to increase the supply and reduce the selling price of the product, but also to raise the demand relative to the supply of one or more of the factors of production the industry uses. This will raise the price of those factors of production and thus the industry's unit cost of production. Thus, in this case too, the industry's rate of profit will fall toward the general level both because of a fall in its selling price and a rise in its costs.

By the same token, the industry whose product is in decreased demand and whose rate of profit has been depressed below the general level, will, as before, expe-

rience an efflux of capital. The effect will be both to reduce the supply of its product and the demand for one or more of the factors of production it uses. Thus, while the selling price of its product tends to rise, the prices that constitute its costs of production tend to fall. Its rate of profit, therefore, tends to be restored to the general level as the result of both of these phenomena.

It should be realized that this discussion implies that the uniformity-of-profit principle operates even in circumstances in which it is physically not possible to increase the production of a product because one or more of the necessary factors of production simply does not exist. For example, if there is an increase in demand for a particular wine, which must be made from grapes that can be grown only on a small quantity of land on which very special growing conditions exist, the first effect will be a rise in the price of the wine and in the rate of profit to be made in producing the wine. As usual, additional capital will now tend to be invested in producing the item, but the effect of the additional investment in this case will simply be to raise the price of the grapes and the vineyards. The rate of profit in this case will be brought down to the general level without an increase in supply and fall in the price of the product. It will be brought down by virtue of the rise in the prices of the factors of production and in the amount of capital that must be invested in order to earn any larger amount of profit. The winery will not be able to go on making an above-average rate of profit, because it will have to pay a correspondingly higher price of grapes. The vineyard, that receives the higher price of the grapes, will not be able to go on making a higher rate of profit, because the value of the vineyard will increase to the point that its larger amount of profit, earned on the more valuable grape crop, is divided by a correspondingly larger amount of capital that must be invested in order to purchase such a vineyard. If, of course, the demand for the wine later falls, the result will be a fall in the price of the grapes and in the value of the vineyard, which will once again tend to establish a rate of profit on a par with the general rate.

Still another factor working to establish a uniform rate of profit is changes in the percentage of capacity at which plant and equipment are operated, or, for short, changes in the operating rate of firms. Indeed, it is possible, within limits, that this factor can work even in the absence of changes in the price both of the product and of the factors of production used to produce it.

Whenever there is an increase in demand for the product of an industry which possesses unused plant capacity, the effect is to make that industry operate at a higher level of capacity. By the same token, the effect of a decrease in demand is to cause the industry to operate at a lower level of capacity. Even if the price of the

product does not change, the change in the extent to which plant capacity is utilized makes the average profit margin in the industry vary in the same direction as the change in demand. This is because utilizing plant capacity at a higher rate spreads such fixed costs as depreciation quotas over more units of product and thus reduces unit costs. Thus the profit per unit and the average profit margin increase. Furthermore, in causing a higher operating rate at unchanged selling prices, the rise in demand also causes a rise in the rate of capital turnover, inasmuch as a larger physical volume of goods sold at the same prices represents greater sales revenues. While sales revenues are markedly greater, the size of the capital invested in the plants operating at higher rates increases only by the necessary increase in working capital—that is, the capital invested in such things as inventory and work in progress. This means that the increase in capital almost certainly takes place in much smaller proportion than the increase in sales revenues. Thus, on the strength both of a higher profit margin and higher capital turnover ratio, the rate of profit on capital invested in the industry necessarily increases as the demand for its products rises.¹² Of course, for the same reasons as just given, but working in reverse, the rate of profit on capital invested in an industry necessarily falls when a fall in demand causes operation at a lower level of capacity.

On the basis of such facts, a rise in the demand for a product may be accompanied by an above-average rate of profit simply by virtue of a rise in the operating rate of the industry, without a rise in the selling prices of its products. In response to this higher rate of profit, additional capital is invested, and the effect of the additional investment is to reduce the rate of profit of the industry, back toward the general level, merely by virtue of the consequence being a reduction in the rate of capacity utilization. Similarly, the withdrawal of capital from an industry with a below-average rate of profit can restore the rate of profit merely by virtue of raising the operating rate of the plant and equipment that remains. This mechanism of adjustment can exist in an industry which normally maintains the same selling prices so long as it operates within some defined range of capacity, and which experiences a pronounced tendency toward a rise or fall in its average rate of operations due to changes in demand. Before the rise in demand is such as to outstrip its ability to meet it at the prevailing prices of its products, it adds to its capacity and meets the now higher level of demand with additional capacity. The advantage to the firms which do this is that it forestalls the possibility of competitors or potential competitors seizing the opportunity of meeting the additional demand. In that case, not only would the rate of profit of the firms which undertake the expansion come back down, but their share of the

market would be reduced as well. Likewise, before a declining demand goes too far, it may be accompanied by decisions not to replace plant and equipment otherwise coming due for replacement.

Thus, changes in demand may result in changes in the rate of profit leading in the usual way to changes in investment and a resulting movement of the rate of profit back to the going rate without the necessity of changes in the price of the product.¹³

It must be stressed that the uniformity-of-profit principle describes a *tendency*, never an actually existing state of affairs. This is because before a uniform rate of profit can be achieved in all branches of production, new changes occur, requiring a different pattern of investment of capital in the economic system if such uniformity is to be achieved. And before the relative size of the various industries can be adjusted to conform with that pattern, still further changes occur, requiring yet another pattern of investment of capital, and so on without end. Thus, the economic system never comes to rest in an actual state of final equilibrium, whose existence is an essential condition of the existence of a uniform rate of profit. The economic system is merely tending toward such an equilibrium, which is itself constantly changing.¹⁴

The final equilibrium toward which the economic system tends constantly changes because of continuous changes in such phenomena as the state of technology and supply of capital equipment, population and its distribution in terms of age and sex, climate and weather conditions, usefulness of various areas for mining, and so on.¹⁵ The uniformity-of-profit principle is nonetheless fully real. Its reality is confirmed by the fact that definite changes *must* occur in order to prevent its realization. Among the most important of such changes, of course, is, as we have seen, the continuous innovation required to stay ahead of competitors, whose emulation of one's earlier improvements would, in fact, drive one's profits down to the average rate if one did not continue to innovate.

Permanent Inequalities in the Rate of Profit

In addition to the fact that there is constant change in the final state of equilibrium toward which the economic system tends, there are factors operating to create permanent inequalities in the rate of profit even in a state of unchanging final equilibrium. In a sense, inequalities in the rate of taxation can be described as such a factor, in that in order to earn equal after-tax rates of profit, the more-heavily-taxed industries will require a higher pre-tax rates of profit than the less-heavily-taxed industries.

If a branch of business is subjected to any other form of legal disability, in particular, if it is simply made

altogether illegal, then that fact will operate to make it earn a permanently higher rate of profit than other branches of business. This is because no one will engage in that line of business unless, over and above the going or average rate of return, the profits provide compensation for the risk of incurring the legal penalties imposed. Thus, the illegalization of such activities as gambling, prostitution, and narcotics, for which, however regrettably, a substantial portion of the population is ready to pay, has the ironic effect of enabling those who are prepared to engage in them and who, in addition, are willing to break the law, to earn premium incomes.

Apart from all government intervention, there is also the fact that in many cases the profits earned must compete with the wages and salaries that the businessmen involved could have earned by working elsewhere, as employees. This phenomenon is especially important in the case of small, unincorporated business firms, in which much or even all of the physical labor performed is performed by the owners. When expressed as a percentage of the capital invested, the profits of such firms tend to constitute a far higher percentage than the profits of larger-sized firms, in which comparable labor is performed by paid employees. Thus, for example, a drug store chain, with pharmacists and branch managers who are paid employees, will tend to earn the same rate of profit as the average department store chain, automobile company, or steel company. But a small, independently owned drug store, in which the owner performs the labor of a pharmacist and manager, will tend to earn a rate of profit that is high enough to include compensation that is comparable to what the owner could earn in these capacities if he worked as the paid employee of a chain. The same principle, of course, applies to all other small businesses in which the owner performs labor that elsewhere is performed by paid employees.¹⁶ It is possible that because of the satisfaction derived from owning one's own business, the profits in these cases, while substantially higher in terms of a rate of profit, nevertheless fall somewhat short of fully compensating for the wages or salary that could be earned working elsewhere.

A permanent inequality in the rate of return on capital invested can exist between the rate of profit in the narrower sense and the rate of interest.

Whenever the rate of profit is spoken of, without qualification, it should be understood as reflecting profit *gross* of interest payments—that is, prior to deduction of interest payments. The prospective rate of profit in this sense is what determines whether or not it is worthwhile to pay any given rate of interest. For example, in deciding whether or not it pays to borrow a million dollars at a 10 percent rate of interest, a businessman will wish to know

what rate of profit he can make by investing that million. It will pay to borrow only if the prospective rate of profit is somewhat greater than 10 percent.

The rate of profit in this sense, or, as it is often called, the rate of return on capital invested, can be calculated in any given case simply by adding interest payments back to profits net of interest, and then dividing by the total of the invested capital that is owned by the business itself plus the borrowed capital the business uses. By the same token, a rate of profit in the narrower sense can be found by dividing the profit net of interest exclusively by the invested capital that is owned by the business itself.

The following example makes these distinctions clear. If a business borrows \$1 million at a 10 percent rate of interest, and already has \$1 million of invested capital of its own, and earns a profit gross of interest of \$220 thousand, its rate of profit—its overall rate of return on the total capital invested of \$2 million—is 11 percent. At the same time, its rate of profit in the narrower sense of profit net of interest, divided only by its own invested capital, is 12 percent.

We should view the relationship between the rate of profit in the narrower sense and the rate of interest in the light of the following: Equity investors and lenders, or, in a corporate structure, stockholders and bond and note-holders, come together as classes of partners, each with special ownership rights, and jointly invest their capitals in enterprises. The lenders agree to receive a fixed and limited return on their capitals on condition that the capital of the equity investors serve as a buffer between them and any below-average profits or outright losses which the enterprise as a whole might suffer. The equity investors agree to allow their capital to serve as such a buffer, and have claim to everything the enterprise may earn after meeting its contractually fixed obligations to the lenders. The total investment in the enterprise may then earn the average rate of profit, an above-average rate of profit, or a below-average rate of profit, including an outright loss. As a rule, any above-average rate of profit earned on the investment as a whole will accrue to the equity-capital investors; and when considered as a part of the rate of return on the equity capital, will magnify this rate of return to the degree that the equity capital represents a smaller percentage of the total capital, i.e., to the extent that it is leveraged. To the extent that the investment as a whole fails to earn as much as the average rate of profit, the failure is borne first by the equity investors, who may not only earn no return whatever, but may also lose the full amount of their capitals, and only then by the lenders. And this reduction in the rate of return to the equity capitalists will be magnified to the degree that the equity capital represents a smaller fraction of the total capital, that is, to the extent that it is leveraged.

As these remarks suggest, while the rate of profit gross of interest is the determinant of the rate of interest, it is not necessary that the two be equal. It is likely that the greater degree of certainty and safety attaching to loan capital and its return will depress that return somewhat below the average rate of profit inclusive of interest. Indeed, in conditions of rapid economic progress and keen competition in the process of improvement, the rate of profit in the narrower sense tends to be significantly and permanently higher than the rate of interest. In such conditions, the general rate of profit on capital as such may be relatively high, for reasons to be explained in Chapter 16. Yet high rates of profit are available only to those who are capable of introducing improvements or at least rapidly adapting to them. All others, if they are prudent, will be content to accept a much lower and, for them, much more secure rate of return, in the form of interest.

In the light of the preceding discussion, the frequent complaint that one can borrow money only to the extent that one already has it, appears absurd. Nothing could be more natural or reasonable than that one must have money in order to borrow money. This is because if one is to acquire the funds of others at a fixed, limited rate of return, one must have the means of ensuring that these funds and the promised return are protected. In essence, all loans are margin loans. Only to the extent that the borrower himself possesses capital can he provide a margin of safety on a larger total capital. It is thus no less absurd to complain that people cannot borrow funds except to the degree that they already possess funds than it would be to complain that one cannot speculate on the stock exchange beyond the degree that one can provide the necessary margin. Every entrepreneur must himself be a capitalist or he must find a capitalist who is willing to be his partner in entrepreneurship. In every venture in which lenders have capital there must also be equity capital. To secure more borrowed capital, there must be more equity capital.

2. The Tendency Toward a Uniform Price for the Same Good Throughout the World

A second principle of price determination, similar and closely related to the uniformity-of-profit principle, and which also plays a major role in coordinating the division of labor, is that *in a free market there is a tendency toward the establishment of a uniform price for the same good throughout the world.*

The basis of this principle is the fact that any inequality in the price of the same good between two markets creates an opportunity for profit. In order to profit, all one

need do is buy in the cheaper market and sell in the dearer market. The very fact of doing this, however, acts to reduce the inequality in price. For the additional buying raises the price in the cheaper market and the additional selling lowers it in the more expensive market. The process tends to continue until the inequality in price between the two markets is totally eliminated and a uniformity of price achieved.

The reason that uniform prices among different geographical markets are not actually established is mainly the existence of transportation costs. The existence of these costs means that before a price discrepancy between two markets becomes profitable to exploit, it must exceed these transportation costs. These costs, however, then set the limits which geographical price discrepancies do not tend to exceed. Or, to put it positively, the price of the same good tends to be uniform throughout the world except for transportation costs between markets.

(In the case of goods sold by a single seller, such as those with brandnames or under patent protection, the principle may take the form that the wholesale price in the market that imports tends not to exceed the retail price in the market that exports, plus transportation costs. So long as the good is publicly available to all comers at the retail level in any given country, its wholesale price in a free market cannot for long be greater elsewhere by more than the costs of transportation. Thus, for example, in a free market, while American pharmaceutical manufacturers might charge less for various patented drugs in Mexico than in the United States, because of the lower incomes and thus smaller demand for drugs in Mexico, they would not be able to do so for very long by more than corresponded to this variant of the principle.)

The significance of the principle of the tendency toward a geographic uniformity of prices is very great. Its operation explains, for example, why local crop failures in a free market do not result even in significant scarcities, let alone famines. The effect of a failure of the local grain crop, say, is to begin raising the price of grain in the local market. Once the local price of grain exceeds prices in outside markets by more than transportation costs, it becomes profitable to buy in those outside markets and sell locally. The effect is that the reduction in the local supply is almost entirely made good by drawing on the production of the rest of the world. Consequently, instead of a disastrous reduction in the local supply and an enormous rise in the local price, there is a modest reduction in the world supply and a modest rise in the world price of grain.

A good analogy to what happens is provided by the physical principle that water seeks its level. Imagine that you have just filled an ice tray—the kind in which water

is able to flow around and underneath the plastic or metal insert that marks off the separate compartments for the ice cubes. If you now remove water from one compartment of the tray, you will not reduce the water level in that compartment by the amount of water you take from it. You will reduce the water level in that compartment and in the whole tray very slightly, because the loss from the one compartment will be spread over the whole tray.

In just the same way, if half the wheat crop of France were lost, the supply of wheat in France would not fall by half. On the contrary, the supply in France and in the whole world might fall by 2 or 3 percent—or however much of a decline the French loss represented in the world supply.

Water seeks its level by virtue of the force of pressure. It moves from places of higher pressure to places of lower pressure. Commodity supplies seek their level by virtue of the attraction of profits. They move from places of lower prices to places of higher prices, in the process equalizing prices as the movement of water equalizes pressure.

It should be realized that the principle of the tendency toward a geographical uniformity of prices is not only descriptively analogous to a law of physics, but, as far as the ability of governments to act is concerned, has the same *existential status* as a law of physics. (And so, incidentally, do all the principles of economics.)¹⁷ That means it is impossible even for the world's most powerful governments to annul its operation. Governments can frustrate its operation, but even in the cases in which they do so, they cannot annul its operation. The existence of the principle is confirmed by the very attempts to frustrate it, because to frustrate it, definite means must be adopted, which are necessary only because the principle exists, and is working. For example, governments may adopt tariffs, or they may prohibit imports or exports altogether, and in that way stop the equalization of prices. But why must they resort to such measures? The answer is because the principle does exist and is at work even in a controlled economy. Controls of a specific kind are needed to counter it. There is no difference here between economics and the example of water seeking its level. We can make ice trays in which each compartment is totally insulated from the others. That does not contradict the principle that water seeks its level. It confirms it, because the insulation is required only because water does seek its level, and for some reason one wishes to stop it from doing so. It is the same way with all economic laws and government attempts to frustrate them.

Why the Arab Oil Embargo Would Not Have Been a Threat to a Free Economy

The principle that in a free market there tends to be a

uniform price for the same good throughout the world has major application to the Arab oil embargo of 1973–74. The principle shows that if the United States had had a free market in oil when the Arabs imposed their embargo, our oil supplies could not have been seriously jeopardized.

Let us think back to the time of the embargo, and imagine that everything else is the same except that the United States has a free market in oil.

The Arabs now launch their embargo. The immediate effect is that a large part of the oil supplies of the northeastern United States—the major importing region and the one dependent on the Arabs—is cut off.

In a free market, no sooner would this have happened, than the price of oil and oil products in the Northeast would have begun to rise. Once prices in the Northeast came to exceed those in the rest of the country by more than the costs of transportation, supplies would have moved from the rest of the country to the Northeast. The effect would have been largely to replenish supplies in the Northeast and to reduce supplies somewhat in the rest of the country. The reduction in imports from the Arabs, in other words, would have been spread over the whole country instead of being concentrated in the Northeast, where it threatened to cripple the economy of the region. In this way, its impact would have been minimized. Prices in the Northeast would have been held down by the inflow of the new supplies, and those in the rest of the country raised up by the shipments to the Northeast.

In fact, the higher level of oil prices in the Northeast and in the country as a whole would have acted as a magnet to supplies of oil from outside the country. The same motives that would have impelled a Southern or Midwestern oil producer to send additional supplies to New York or Boston would also have impelled a Venezuelan or Nigerian producer to do so. In fact, additional imports could have come from the most remote places. As the rise in prices in the Northeast pulled up prices in the rest of the country, it could very well have become profitable to start shipping additional supplies to the West Coast from oil-producing areas like Indonesia, thereby freeing more of domestic production for supplying the Northeast.

Indeed, the United States could have gone on benefiting from Arab oil! This would have occurred simply as a result of expanding the import of refined petroleum products made from Arab oil in places not subject to the Arab embargo. For example, if the Arabs continued to supply Spanish refineries, say, and the price of refined products had risen in the United States, those refineries would have diverted more of their output to the United States.

It thus becomes apparent that within a fairly short time

an embargo by the Arabs against oil shipments to the United States would have had very little effect on the supply of oil in the United States. To the extent that the United States had been importing Arab oil, it would, for the most part, merely have changed importers, and, for much of the rest, it would even have continued to benefit indirectly from Arab oil, in the form of importing refined products made from Arab oil in non-Arab countries.

The reason the Arab embargo did threaten us was the existence of our price controls on oil and oil products. These price controls had been imposed by President Nixon in August of 1971, as part of a temporary general price freeze, and then remained in force after almost all of the other price controls were removed. Thus, when oil supplies to the Northeast were cut off by the embargo, price controls prohibited the people in the Northeast from bidding up oil prices. The people in the Northeast were therefore made powerless to bring about the shipment of additional supplies from the rest of the country. In the same way, price controls prohibited the people of the United States as a whole from bidding up prices, with the result that it was not possible to bring about stepped-up imports from non-Arab sources. The effect of our controls was to cause the reduction in imports from the Arabs to be experienced with full force at its initial point of impact and to make it impossible to obtain replacement imports. Our price controls paralyzed us—they made it impossible for us to take the actions needed to deal with the situation.

Indeed, because of our price controls, we were not only prevented from finding replacement imports for the loss of Arab imports, but were forced to lose imports from non-Arab sources as well! This happened because other countries in the world, such as West Germany, became better markets in which to sell oil than the United States. As a result, our non-Arab foreign suppliers were led to sell more of their oil to those countries and less to us. Because of our price controls, we tied our hands in the international competition for oil, and made it possible for countries far poorer than ourselves to outbid us for oil we had normally consumed.

There is more to say about why a free American economy would have had nothing to fear from an Arab embargo.

In late 1973 and early 1974, the Arabs were apparently threatening to cut off oil supplies to the world. There was near panic over whether they would do so. There seemed to be no solution except either to give in to their demands, whatever they might be, or go to war with them.

If we had had a free economy, the only lasting effect of any embargo the Arabs might have launched against the rest of the world would have been to strengthen our

oil industry at the expense of their oil industry.

To understand this point, let us assume that the American economy had been free of all price controls in 1973 and that the Arabs had launched their embargo with the serious intention of cutting off their supply of oil to the world. Let us assume that the worst fears people had at the time came true and that the Arabs simply stopped selling oil to anyone, in an effort to blackmail the world into doing their bidding.

The effect, of course, would have been a skyrocketing of the price of oil.

But observe. The Arabs wouldn't have gotten the benefit of the higher price, because *they* wouldn't have been selling any oil.

The benefit of the higher price of oil would have gone to the non-Arab producers, mainly to the producers in the United States.

The American oil companies in that case really would have made fabulous profits. They might have made profits at a rate fast enough to double their capitals in a single year, or less. They would have made the kind of money the Arabs made.

In the face of the Arabs' withdrawal from the market, a tendency would have set in to reestablish the United States as an oil exporter, because Western Europe and Japan would have had to turn to us. However much prices skyrocketed here, they would have skyrocketed still more there. Instead of our high prices pulling oil in, we would have begun to ship oil out, in response to their still higher prices. Billions of dollars would have begun to flow from Western Europe and Japan to the United States, not to Iran or Saudi Arabia.

With vast profits starting to pour in from the rest of the world and, of course, from American buyers too, huge sums would have become available for every kind of oil and energy project in the United States. It would not have taken long, with such profits, for the domestic oil industry to have been entirely rejuvenated and established on an enormously larger scale than ever before, and who knows what other new sources of energy along with it.

Now consider the Arabs. While the American oil producers would have been making money hand over fist, the Arabs would have been starving for lack of income. In this context, it would have been virtually certain that the Arab alliance would soon have broken up. The less fanatical Arab countries would soon have resumed the sale of oil in order to cash in on the profits. Probably, in very short order, all of them would have begun selling again. So, in fact, the supply of oil in the world would almost certainly not have been drastically reduced for very long, despite whatever intentions the Arabs may originally have had. And, therefore, the United States would not, in fact, have had to switch for very

long, if at all, from the role of an oil importer to the sudden role of an oil exporter. But to whatever extent the Arabs had delayed in resuming the sale of oil, the effect of their action would have been to impoverish themselves while enormously enriching the oil industry in every other country, especially the United States.

In the years that followed, the American oil industry would have been bigger and richer. American oil production and the production of other forms of energy in the United States would have been expanded because of the additional profits that American firms had earned. Very possibly, a year or two after the embargo, the price of oil would have fallen below its level in the period before the embargo, because of expanded American production. The oil industry at that point might have run at losses for a while. The American firms would have been able to cover their losses out of the profits the Arabs had handed them. The Arabs would not have been able to cover their losses as easily. Consequently, the effect of the whole process would have been a larger American oil industry and, quite possibly, a smaller Arab oil industry.

This is what economic freedom would have accomplished.

The question might be raised of just how high oil prices could have gone during the Arab embargo if we had not had price controls. It is impossible to answer such a question with any accuracy. Perhaps for a brief period we might have had very high prices of oil and oil products. While they lasted, such prices would certainly have represented a hardship for many people, the author of this book included. But later we would have had lower prices than we had, thanks to a larger domestic oil industry and energy industry in general. Indeed, the preceding discussions make clear that the rise could not have been very great for very long, and that in a short time, oil prices would have begun to fall, just as has turned out to be the case since the repeal of the price controls. Furthermore, as we will see, even while a high price lasts, the real problem is not the high price, but the scarce supply. No one's hardship is alleviated by a low price for goods he cannot buy, which is always the effect of price controls. If we in fact have a scarcity, and consumption must be restricted, then, as will be shown, the high price is necessary and positively beneficial, because it leads people to restrict their consumption in the ways that are least damaging to themselves.

The policy of price controls on oil during the embargo, therefore, cannot even be said to have sacrificed our long-run economic well-being to our short-run economic well-being. It sacrificed both our long-run and our short-run economic well-being.

Tariffs, Transportation Costs, and the Case for Unilateral Free Trade

The existence of tariffs modifies the operation of the principle that the price of a good tends to be the same throughout the world in exactly the same way as does the existence of transportation costs. Namely, it allows the prices of goods to differ between two markets by a wider margin, equivalent to the existence of additional transportation costs—that is, by the sum of transportation costs between the two markets plus the amount of the tariff. Now, only when the price of a good in one market comes to exceed its price in another market by more than the sum of transportation cost plus tariff, does it pay to buy in the cheaper market and sell in the dearer market. This, of course, operates to drive the discrepancy in price to the point where it no longer exceeds the sum of transportation cost plus tariff.

The fact that tariffs have the same effect on price differentials between markets as do transportation costs, and can be analyzed as the equivalent of additional transportation costs, implies that a country must benefit from a policy of free trade even if it adopts that policy *unilaterally*, with its citizens having to go on selling their goods in countries that continue to maintain tariff barriers. For a policy of unilateral free trade is analytically equivalent in its effects to a fall in inbound transportation costs while outbound transportation costs remain the same.

In the nature of the case, the inhabitants of a territory must benefit from the fact that the cost of transporting goods to them is as low as possible. The fact that it is lower than the cost of transporting goods from them to other areas can make no difference. If, for example, they were fortunate enough to live in a territory toward whose coast the predominant winds blew or the ocean current flowed and which, accordingly, found itself with correspondingly low inbound transportation costs, they would benefit from that fact, even though inbound transportation costs were thereby rendered less than outbound transportation costs. The fact that it is not equally less costly for their goods to reach others does not take away the advantages to them of others' goods being able to reach them more cheaply. It would be the height of absurdity on their part to demand that inbound freight be rendered artificially more costly, say, by requiring inbound ships to carry extra ballast, in order to equalize the transportation costs of inbound and outbound freight.

The situation is exactly the same with regard to a policy of unilateral free trade or a country having tariffs lower than the tariffs of the countries with which it trades. To insist that one's own country have tariffs so long as the countries its citizens sell to have tariffs, or have tariffs that are as high as the tariffs of those countries, is to

demand the equivalent of raising inbound transportation charges merely because they happen to be lower than outbound transportation charges.¹⁸

3. The Tendency Toward Uniform Prices Over Time: The Function of Commodity Speculation

In a free market there is a tendency toward the equalization of the price of a good in the present with the expected price of that good in the future. For example, there is a tendency for the price of wheat or crude oil or whichever, today, to be equal to the expected price of wheat or crude oil or whichever next month, six months from now, or next year. This principle applies to any good that is capable of being held in storage.

The basis of this principle is the familiar fact that any discrepancy in price creates an opportunity for profit, the exploitation of which reduces the discrepancy. If, for example, wheat is expected to be more expensive six months from now than it is today, then speculators begin to buy wheat at today's comparatively low price for the purpose of storing it and later selling it at the comparatively high price that is expected to exist in the future. The effect of their action is to raise the price of wheat in the present, and, by enlarging the supply available in the future, reduce the price of wheat in the future. As a result, the present and expected future prices are brought closer together.

The present and expected future prices will never actually be equalized, for two important reasons. First, there are costs of storing any commodity. In addition, since every business must yield the going rate of profit, if it is to continue in existence, it is necessary to earn as good a rate of profit in storing commodities as in any other line of business. Consequently, the actual relationship between present and future prices is that they tend to differ by no more than the costs of storage plus an allowance for the going rate of profit on the capital that must be invested in the storage.

The practical significance of this principle can be seen in the following example. Assume that the wheat harvest is one-twelfth below the size of the average annual harvest. It is therefore necessary to stretch what would normally be an eleven months' supply of wheat over twelve months. If the price of wheat did not rise at harvest time, the consumption of wheat and wheat products would go on at the usual rate, requiring a more severe restriction of consumption later on. Imagine that the price did not rise until after ten months had gone by, during which consumption had occurred at the usual rate. In that case, two months would be left to go until the next harvest, and it would be necessary to stretch the remaining supplies, equal to only one month's usual consump-

tion, over that period. By the rise in price being delayed this long, one month's supplies would have to be made to do the work of two, instead of eleven months' supplies doing the work of twelve. The rate of consumption would have to be cut in half instead of merely by one-twelfth. It is the same in principle for all shorter periods during which the rate of consumption is excessive. Always, an excessive rate of consumption in the earlier months must be balanced by a more severely reduced rate of consumption in the later months.

The existence of speculation on future prices prevents such calamities and minimizes all such imbalances in the rate of consumption. Speculators anticipate the future prices of commodities and buy or sell the commodity in question for the purpose of profiting from every discrepancy between the present price and the prices they expect to exist in the future. In our example, the activity of the commodity speculators would serve to bring about the minimum necessary restriction in the rate of wheat consumption. For if they see that in the absence of their activity prices will reach famine levels in the future, or levels reflecting a severe scarcity, or even any level whatever that exceeds the present price by more than the costs of storage and the going rate of profit, they begin to buy the commodity in question for the purpose of profiting from the future high price. Their additional buying raises the price of the commodity in the present and thus restricts the rate of its consumption. Later, as the future unfolds, the goods in the hands of the speculators constitute a larger supply and serve to reduce prices in comparison with what they would otherwise have been. The activity of the speculators therefore serves to transfer supplies from a period in which they are less urgently needed, as indicated by their lower price, to a period in which they are more urgently needed, as indicated by their higher price. In this way, it brings about the optimum rate of consumption of limited supplies.

Speculative activity, of course, is not limited to anticipating just future scarcities. Rather, it seeks in general to balance consumption and production over time by accumulating stocks of commodities and regulating their rate of consumption. If it is anticipated, for example, that a future harvest will be larger than originally forecast, and thus that the price of wheat in the future will be lower than originally expected, the activity of the speculators will bring about a lower price immediately. In anticipation of the lower future price, some of the speculators will begin to sell their holdings of the commodity now, in order to find a more profitable employment for their capitals. As a result of their sales, the price begins to fall right away. As a consequence of the lower price, the rate of consumption in the present is expanded. In this case, the effect of speculative activity is to permit present

consumption to expand in the knowledge that larger future production than originally expected necessitates the holding of smaller present stocks.

Much speculative activity occurs on organized commodity exchanges. However, only a relatively small number of basic commodities are traded on the exchanges—principally various agricultural commodities and nonferrous metals. For the rest, speculation is largely limited to those who are engaged in the actual production or use of the commodity.

It should be realized that every businessman is a commodity speculator when he decides what size inventory to hold of his product or materials and whether it is a good time to increase or decrease the size of his inventory. For he is basing his decision on a comparison of present prices and the prices he expects to exist in the future. In the same way, every consumer engages in commodity speculation when he decides to buy more or less than his normal requirements on the basis of a comparison of present prices with the prices he anticipates in the future.

The speculative activities of businessmen and consumers serve to equalize present and future prices in additional ways than the one we have considered. For example, if, in anticipation of higher prices, businessmen simply hold back on selling their inventories, they are decreasing the supply available in the present and increasing the supply available in the future, which, of course, acts to narrow the discrepancy in price. By the same token, if businessmen or consumers step up their purchases in the present, in anticipation of higher prices in the future, then, to that extent, their demand for the item in the future will be less because it will already have been provided for. In this case, a larger present demand and smaller future demand act to reduce the discrepancy in price.

Like almost every economic activity that goes beyond manual labor, commodity speculation is frequently denounced. Because speculation transmits the higher prices expected to exist in the future to the present, it is denounced as the cause of the higher prices. What is overlooked in this accusation is that the supplies accumulated as a result of speculation must ultimately be used, and at that time they necessarily act to reduce prices—because either they are put on the market and sold, thereby increasing the supply of the commodity, or, by sparing their owners the need to purchase, they reduce the demand for the commodity. Moreover, if the speculators are mistaken—if they raise the present price and there is no independent cause of a higher price in the future—they pay the penalty for their mistake: they have bought at high prices and must later sell at low prices; or they have stocked up at high prices when they might later have

bought at low prices; or, in holding back their supplies in the hope of selling at higher prices, they end up having to sell at lower prices than they could have obtained by not holding back.¹⁹

It is necessary to point out that the connection between present and expected future prices is broken in conditions of increases in production and declines in price. In such conditions, the ability to reduce prices in the present by selling out of accumulated stocks reaches its limit once those stocks have been reduced to their necessary minimum. At that point, if prospective future prices are lower still, no mechanism remains which is capable of driving present prices down any further and thus coming back into correspondence with the prospective future prices. (There is no basis for a decline in demand in cases in which the item needs to be used in the present, such as food. There is also no basis for any general or widespread decline in demand insofar as the falling prices that are expected to result from increased production will enable people's incomes to go further, for this gives them the prospect of being better off in the future. In these conditions, people are in a continually better position to buy.) Thus it becomes possible for prospective future prices to fall below present prices by almost any amount. This in fact is regularly the case with respect to agricultural commodities in the months preceding the harvest. Their prospective prices during the coming harvest are almost always sharply below their current prices, precisely because of the inability to make significant further sales out of accumulated stocks, which stand at their low point in the period before the harvest. And the very fact that the stocks do stand at a low point is also responsible for the prices in the months just prior to the harvest standing at a high point.

The connection between present and future prices is established mainly by the accumulation of stocks to take advantage of prospective higher prices in the future. Declines in present prices based on the anticipation of lower future prices occur in a context in which the holding of significant supplies for the future is still necessary, but in which it is possible for the magnitude of the supplies held to be less.

Rebuttal of the Charge That the Oil Shortages of the 1970s Were “Manufactured” by the Oil Companies

Our knowledge of speculation can be applied to the charge that the oil shortages of 1973–74 and 1979, were “manufactured” by the oil companies. This was an accusation which was repeated again and again in the press and on television in those years. The accusation represents a classic case of economic ignorance, and is thus well worth analyzing.²⁰

The proof offered that the oil companies were artificially creating the oil shortage was the allegation that their storage depots were full of oil. I remember one television news story in the 1973–74 crisis, filmed at an oil company tank farm, in which the reporter pointed to the tanks, said he had personally seen that they were full, and, therefore, that there could be no real shortage of oil, but just an “artificial” one created by the oil companies.

The reporter, his editor, station, and network evidently forgot, or did not know, the major news item of the time, which was the prospect that in the coming months the United States would be deprived of a significant part of its customary imports of oil, while having to meet the possibility of a long, severe winter. The tanks and storage depots most certainly *should* have been full, *in anticipation* of that terrible prospect. Any fullness of the tanks and depots was not, as the news media claimed, a proof of the abundance of oil, but of its *prospective scarcity*. (The reader should imagine what it would mean if the day ever came when he thought it necessary to fill every spare inch of his kitchen with food. His large stockpile would not be a proof of the abundance of food, but of the prospective scarcity of food.)

Apparently, the media were simply unaware of the need to hold supplies of oil for future sale. For it appears that they would have been satisfied with the genuineness of the shortage only if their reporters had visited the tank farms and found them empty. By that time, however, it would have been too late: millions would have died from the lack of oil.

The unfortunate fact was, however, that the oil company storage depots and tank farms were *not* full. The media erroneously inferred from their observation of a large quantity of oil at some tank farms that there must be a large supply of oil in the country. Their logic was the same in principle as that of someone travelling to an impoverished country like India and seeing a few warehouses full of food, and then concluding that there is a large quantity of food in the country. In reality, because of price controls, the stocks of crude oil, gasoline, and residual fuel oil in the United States in the period from October 31, 1973, to April 1, 1974—the time of the oil crisis—were all substantially less in most months than their respective averages had been for that period of the year over the preceding five years; distillate fuel (home heating oil) was the only major oil product whose stock had been increased. Overall, that is, if one simply adds up the number of barrels of crude oil and of the various kinds of oil products, stocks were significantly lower in all but two months, when they were very slightly higher.²¹

The fact that stocks of oil in storage were actually below average in 1973–74 should not be surprising. Such a result is to be expected from price controls. It is implied

in our example of the deficient wheat harvest in which the price does not rise. It is only necessary to realize that price controls not only induce buyers to buy up commodities too rapidly for supplies to last, but also induce sellers to sell them too rapidly. Sellers are led to sell too rapidly because it is more profitable to sell goods at the fixed, controlled price in the present rather than in the future. By selling in the present, a seller saves storage costs and can earn profit or interest by investing the sales proceeds. If he is going to have to sell at the controlled price, it pays him to sell as soon as possible and simply put the money in the bank if necessary.²²

The only reason that stocks of distillate oil were built up in the crisis period was that the government ordered it. Distillate stocks had declined sharply in early 1973, as the result of price controls, with the result that shortages began to appear even then. The government feared vastly worse shortages in the winter of 1974: it feared the prospect of people freezing to death.

It should be understood that if we had not had price controls, any build-up in stocks of oil that would have occurred, would not have caused a shortage, even though it reduced the supply of oil currently available. In the absence of price controls, the build-up would have raised the current price of oil. At higher prices, people would have economized on their use of oil products to whatever extent it was necessary to reduce current consumption. Of course, higher prices would also have pulled in supplies from other markets, making the necessary reduction in current consumption that much less. As will be shown in later discussion, anyone able and willing to pay the higher current prices would have been able to buy whatever oil products he wished. There would have been no shortage in the sense of people being able and willing to pay the asking price of oil but unable to obtain it. Thus, even if there had been a build-up of stocks of oil, as the media claimed, it could not have caused a shortage of oil in the absence of price controls.

In charging the oil industry with “manufacturing” the oil shortage by holding large stocks of oil, the media displayed ignorance in four respects. First, they were ignorant of the fact that, with the exception of distillate, stocks of oil were not actually large, but significantly below normal. Second, they were ignorant of what large stocks of oil would have signified had they existed (or, in the case of distillate, what the large stock did signify)—i.e., proof not of abundance, but of *prospective scarcity*. Third, they were apparently ignorant even of the fact that it is necessary to hold stocks of oil in the first place, for their attitude was, it seems, that so long as oil was on hand, there could be no problem of a lack of it. Fourth, they did not know that in the absence of price controls, no accumulation of a stock could cause a short-

age in the current market.

In their treatment of the oil shortage, the media functioned on the level of men without the ability to think conceptually. They proceeded as though they were unable to make distinctions between quantities that are perceptually large, that is, between a tank farm full of oil, and an adequate national supply. They proceeded as though they were unable to think beyond the range of the immediate moment, that is, to realize the need to hold supplies for future sale. They proceeded as though they were incapable of understanding connections among concrete events, namely, the connection between the prospect of the loss of imports and the need to build up stocks of oil. They proceeded, in short, as though they had never heard of, and were incapable of grasping, a single principle of economics. Only because they functioned at this incredibly low mental level, was it possible for the media to assert that the oil shortage was “manufactured” by the oil companies.

I will have much more to say about this accusation in the pages that follow. I will show that it is correct to say that the oil shortage was “manufactured” and “artificial,” only if one realizes that it was manufactured by the government, through price controls, not by the oil companies and their perfectly natural and praiseworthy desire to earn profits.

4. The Tendency Toward Uniform Wage Rates for Workers of the Same Degree of Ability

In a free market there is a tendency toward an equalization of wage rates for workers of the same degree of ability.

The basis of the tendency toward equality is the fact that men prefer to earn a higher income rather than a lower income, and therefore seek higher-paying jobs in preference to lower-paying jobs. The movement of labor into the higher-paying fields and out of the lower-paying fields reduces wage rates in the higher-paying fields and raises them in the lower-paying fields. The stopping point is an equality of wage rates.

This is not to say that forty- or fifty-year-old workers suddenly give up their work of many years to change to a brand-new occupation in response to a 5 or 10 or even 20 percent difference in wages. No. In view of the costs and the various other problems such workers would have to incur in the learning of new skills, it would not pay them to switch occupations except in cases of extremely large differences in wages—brought about, for example, by their previous jobs being rendered obsolete through technological progress.

The movement of labor from occupation to occupation in response to less-than-gross differences in wage

rates is accomplished in a different way. It is accomplished by virtue of the fact that each occupation continually loses members through death or retirement and must continually be resupplied with young workers. Changes in the flow of young workers into the various occupations produce the same effect as an actual movement of labor between occupations. Where the number of young workers entering an occupation exceeds the number of old workers dying or retiring, the supply of labor in that occupation rises. Where the number of young workers entering an occupation is less than the number of old workers leaving, the supply of labor in that occupation falls.

Now by the time young people are ready to begin preparing themselves for a career, there are very marked differences in their ability and willingness to learn. And, for this reason, the labor force necessarily assumes a hierarchical structure, with the tendency toward an equalization of wage rates being operative only within the respective levels of this structure, not throughout the structure as a whole.

Those with the greatest ability and willingness to learn are potentially capable of performing practically any job. For example, the young man who is capable of learning to be a surgeon is also certainly capable of learning to be a printer. In turn, the young man who is capable of learning to be a printer is also certainly capable of learning to work on an assembly line. Everyone, in other words—the potential surgeon, the potential printer, and the potential assembly line worker—is capable of learning the work of the assembly line worker. But only the potential surgeon and the potential printer are capable of learning the work of the printer. And only the potential surgeon alone is capable of learning the work of the surgeon.

In conformity with the principle contained in this example, let us think of the young people ready to prepare for a career as divided into three broad groups: those capable of entering the professions, those capable of learning to do skilled work, and those capable of learning to do no more than unskilled work.

Such a division of the potential labor force necessarily prevents any tendency toward a general equalization of wage rates. No matter how high the wage rates of the professions may climb in relation to those of skilled and unskilled labor, it is simply impossible for young people who lack the necessary capacity, to go into the professions instead of skilled or unskilled labor. Similarly, no matter how high the wages of skilled labor may climb in relation to those of unskilled labor, there is, again, no way for the young people who lack the necessary capacity, to enter the field of skilled labor instead of unskilled labor. On the other hand, the wages of skilled labor *are* limited

in relation to those of professional-level labor. For as soon as the wages of skilled labor begin to exceed those of professionals, it is possible for young people capable of the professions to enter the field of skilled labor. In the same way, the wages of unskilled labor are limited in relation to those of skilled labor. For as soon as the wages of unskilled labor begin to exceed those of skilled labor, it is possible for young people capable of skilled labor to enter the field of unskilled labor.

It is because of this hierarchical division of the total pool of human talent—of the fact that ability can flow downward to lower channels, but not upward to higher channels, so to speak—that we observe in actual life that the wages of professionals markedly and permanently exceed those of skilled workers, while those of skilled workers, in turn, markedly and permanently exceed those of unskilled workers. And we observe that the wages of the highest-paid skilled workers cannot get very far ahead of the wages of the lowest-paid professionals, nor the wages of the highest-paid unskilled workers very far ahead of the wages of the lowest-paid skilled workers.

This explains inequalities in wages. Let us return to the question of why wage rates for any given level of ability tend to be equal.

Let us consider the wage rates of a number of skilled occupations, for example, the various building trades, such as carpenters, electricians, and plumbers, and other skilled occupations, such as printers, draftsmen, mechanics, and locomotive engineers. All of these occupations, and others of a similar nature, require the same basic level of intelligence and education on the part of the workers. As a result, they are all potentially capable of being performed by the same people. All of them, in effect, can be supplied with labor that is drawn from a pool of human talent on the same basic level. Because of men's preference for a higher income over a lower income, this pool of talent naturally runs more heavily into those occupations which offer higher wages and less heavily into those which offer lower wages. As a result, there is a tendency toward an increase in the supply of labor in the better-paying kinds of skilled work and a decrease in the supply of labor in the poorer-paying kinds of skilled work. Since the effect of the increases in the supply of labor in the initially higher-paying fields is to reduce wages in those fields, while the effect of the decreases in the supply of labor in the initially lower-paying fields is to raise wages in those fields, the discrepancies in wages among the different kinds of skilled labor are narrowed, and thus these wage rates tend toward equality.

In exactly the same way, there is a tendency toward a uniformity of wages among the various unskilled or low-skilled occupations, such as assembly line workers, machine tenders, truck and bus drivers, clerks, steve-

dores, and so on. There is a tendency toward a further uniformity of wage rates among the various professions, such as doctors, lawyers, scientists, engineers, professors, and so on. In these cases, too, the original pool of talent flows into the various channels on its level in accordance with the wages to be made; and, in flowing more or less heavily, lowers or raises those wages, thereby reducing the discrepancies among them and driving them toward equality.

There are, of course, important differences in wages of a permanent nature even within the three broad groups of workers that I have delineated. At each level, there is a tendency for some particular occupations to earn more than others—for example, for doctors to earn more than professors, and for stevedores to earn more than clerks. There are also important differences in earnings within each occupation, especially at the professional level. For example, there are always some doctors or lawyers who earn five or ten times as much as the average of their profession, and there are some printers or mechanics who earn significantly more than others.

These differences are due in part to the existence of further categories of division in human ability. There are those who have the ability and willingness to learn how to be a doctor or lawyer, and others who have the ability and willingness to learn how to be a great doctor or lawyer. In other cases, willingness and ability to learn is not the sole criterion of division. Other factors have to be added. For example, in many types of work, especially unskilled work, it is necessary to possess a significant degree of physical strength. Those who have it are in a narrower category than those who do not and, accordingly, tend to be higher paid. In other cases, workers are differentiated by the special development of other physical or psychological potentials—such as muscular coordination, an ear for music, special visual acuity, and so on. In the case of great athletes, opera singers, musicians, and actors—all the really star performers—the combination of special characteristics is such as to make the labor of these persons virtually unique. As a result, when they are in demand, their earnings do not have any fixed limit in relation to the earnings of others, because no one is able to increase the supply of what they are offering.

For the rest, the differences in wages within the various broad groups are the result of the fact that considerations other than money income are associated with each job. There are such considerations as how interesting or uninteresting is the work, how pleasant or unpleasant are the conditions of the work, how safe or dangerous is it, how regular is the employment, how long and how expensive is the special preparation required, and, perhaps, still other, similar considerations. Considerations

of this kind explain, for example, why scientists tend to earn less, and tax lawyers more, than is commensurate with their respective levels of ability. In the one case, the work itself may be the highest pleasure in life to those who perform it; in the other, it is more likely to be experienced as painfully dull. As a result, those with the necessary ability to be scientists are willing to enter the field even to the point of accepting substantially lower wages in comparison with what they could earn elsewhere. By the same token, people would cease to enter such a field as tax law as soon as that field no longer offered significant monetary advantages over other fields they might enter. The principle that emerges is that any occupation which offers advantages other than income tends to offer correspondingly lower wages, while any occupation that imposes special disadvantages of any kind tends to offer correspondingly higher wages. These discounts and premiums in wages balance the special advantages and disadvantages of the various occupations.

In sum, in a free market there are at least three principles of wage determination at work simultaneously. One is a tendency toward a uniformity of wages for labor of the same degree of ability. A second is a tendency toward unequal wage rates for labor of different degrees of ability—primarily intellectual ability, but also other abilities as well. And a third is a tendency toward the inclusion of discounts and premiums in wages as an offsetting element to the special advantages or disadvantages of the occupations concerned. The combined operation of these three principles helps to explain the full range of the various wage rates we observe in actual life.

Now, as far as it operates, the principle of the uniformity of wage rates is similar in its consequences to the uniformity-of-profit principle. That is, it serves to keep the various occupations supplied with labor in the proper proportions. Too many people do not rush into carpentering and not enough go into printing, say, because the very effect of such a mistake is to reduce the wages of carpenters and raise those of printers. This acts to delimit and counteract the mistake. In addition, the operation of this principle gives to consumers the ultimate power to determine the relative size of the various occupations. If, to continue with the same example, the consumers buy more printed matter and fewer products made of wood, then the effect of the change is to cause the demand for printers to rise and that for carpenters to fall. As a result, the wages of printers rise and more young men are induced to become printers, while the wages of carpenters fall and fewer young men become carpenters.

It should be realized, as this example of the printers shows, that in seeking to earn the highest wages, the individual worker is seeking to do the kind of work the

consumers most want him to do. This is true of every individual who seeks to take the best-paying job he can find at any given level of ability or who seeks to raise his level of ability. For what enables any job to pay more is only the fact that the consumers want its products sufficiently. Let them decide to reduce their demand for its products, and the wages it pays will tend to fall, while if they raise their demand for its products, the wages it pays will tend to rise still higher.

In a free market, within the limit of his abilities, each person chooses that job which he believes offers him the best combination of money and nonmonetary considerations. In so doing, he simultaneously acts for his own maximum well-being and for that of the consumers who buy the ultimate products his labor helps to produce.

Equal Pay for Equal Work: Capitalism Versus Racism

The uniformity-of-wages principle must be understood as implying the existence of a powerful tendency under capitalism toward equal pay for equal work. Despite the prevailing belief that capitalism arbitrarily discriminates against such groups as blacks and women, the fact is that the profit motive of employers operates to eradicate all differences in pay not based on differences in performance. Where such differences persist, they are the result of government intervention or private coercion that is sanctioned by the government.²³

Where the profit motive is free to operate, if two kinds of labor are equally productive, and one is less expensive than the other, employers choose the less expensive, because doing so cuts their costs and raises their profits. The effect of choosing the less expensive labor, however, is to raise its wages, since it is now in greater demand; while the effect of passing by the more expensive labor is to reduce its wages, since it is now in lesser demand. This process goes on until the wages of the two kinds of labor are either perfectly equal or the remaining difference is so small as not to be worth caring about by anyone.

As illustration of the fact that even very small differences in wage rates could not be maintained under capitalism, consider the following example. Assume that white workers of a certain degree of skill are paid \$5 per hour. Assume that black workers of identically the same degree of skill can be hired for just 5 percent less, that is, for just 25¢ an hour less. Assume that a factory must employ 500 workers of this degree of skill. With a 40-hour week, over a 50-week year, this slight difference in hourly wage rates results in a saving of labor cost and a corresponding extra profit per year of \$250,000 if the factory owner employs 500 blacks rather than 500 whites (for $25¢ \times 500 \times 40 \times 50 = \$250,000$).

Even in the case of a small establishment employing

only 10 workers, the annual saving in labor cost, and thus the extra profit attaching to the employment of blacks, would be \$5,000 (since $25¢ \times 10 \times 40 \times 50 = \$5,000$)—enough for the owner to afford a new car every other year or to make significant improvements in his business.

It is doubtful that there are many employers so bigoted as to be willing to indulge their personal prejudice in favor of whites at a cost of \$250,000 per year, or even \$5,000 per year. The clear implication is that even slight differences in wage rates would make the employment of blacks in preference to whites virtually irresistible. Not only would a 5 percent differential in wages not be sustainable, but neither would a 2 percent or even a 1 percent differential. Every such differential would lead employers to hire blacks in preference to whites, and would thus bring about a further rise in the wage rates of blacks and a further fall in the wage rates of whites, until a virtually perfect equality was achieved.

Indeed, profit-seeking employers *qua* profit-seeking employers are simply unconcerned with race. Their principle is: of two equally good workers, hire the one who is available for less money; of two workers available for the same money, hire the one who is the better worker. Race is simply irrelevant. Any consideration of race means extra cost and less profit; it is bad business in the literal sense of the term.

It should be realized that one of the great merits of capitalism is that by its very nature employers are virtually compelled to be oblivious to race. The freedom of competition under capitalism ensures this result. For even if, initially, the majority of employers were so fanatically bigoted as to be willing to forgo extra profits for the sake of their prejudice, they would be powerless to prevent a minority of more rational employers from earning these extra profits. (“Rationality” in this context means not passing moral judgment against a person on the basis of his racial membership and not allowing such a judgment to outweigh the desire for profit. Such a judgment represents a logical contradiction in that morality pertains only to acts open to choice, while a man’s racial membership is not open to his choice. The irrationality is then compounded by the sacrifice of one’s own objective good—the earning of a profit—for the sake of the irrational judgment.) Because of their higher profits, the more rational employers would have a relatively greater income out of which to save and expand their businesses than the irrational majority. Moreover, since they operated at lower costs, they could afford to charge lower prices and thus increase their profits still further by taking customers away from the irrational majority. The result of these factors would be that the more rational employers would tend to replace the less rational ones in economic importance. They would come to set the tone

of the economy, and their attitudes would be transmitted to all other employers, who would seek to emulate their success. In this way, capitalism virtually guarantees the victory of rationality over racial bigotry.

This discussion also provides a rebuttal to the accusation that under capitalism the skills and abilities of groups such as blacks are not utilized. For it follows that the unhampered profit motive leads employers to place the members of all groups in the highest positions for which their skills and abilities qualify them. Consider the following example. Assume that a skilled lathe operator must be paid \$15 per hour, and that black workers who have been taught this skill in a trade school are presently employed as janitors at \$5 per hour. The black workers would almost certainly be willing to change their jobs for a raise to, say, \$10 an hour. Any employer who hired them as lathe operators at \$10 per hour would thereby add \$5 to his profits for every hour of their work, as compared with employing whites. Over the course of a year composed of 50, 40-hour weeks, his extra profit would amount to \$10,000. And this would be on the labor of just one man.

It is obvious that under capitalism, if the skills and abilities of blacks or any one else are being wasted in low-skilled, low-paying jobs, it is to the financial self-interest of employers to change the situation, indeed, to seek out such workers, and in many cases even to incur substantial costs in training them. And it follows that the greater the extent to which a group’s skill or ability is wasted, the greater is the profit to be made by rectifying the situation. For example, if a black with the ability to do the work of a \$100,000-a-year company vice president is working as a \$20,000-a-year clerk, it is even more to the interest of an employer to seek him out and rectify the situation than in the case of the lathe operator working as a janitor. In this case, the employer could double the black worker’s salary to \$40,000, and at the same time add \$60,000 to his own profits by employing him in a capacity commensurate with his skill and ability.

Of course, just as in the initial case, the wages and salaries of blacks brought into the more skilled and higher-level jobs would more and more tend to match those of the white workers performing these jobs. Because as employers competed for blacks, their wages would rise, while, in order to be competitive with the black workers, the white workers would have to accept reductions. Indeed, once the first few blacks or members of other groups in a comparable situation are brought into an occupation in which they were previously unrepresented and succeed in proving their ability by actual satisfactory performance, a dynamic effect ensues. The breaking of the taboo, followed by the visible proof of its lack of rational foundation, changes the way in which such individuals are viewed. The demand for their ser-

vices then greatly increases. (The history of major league baseball provides an excellent illustration. Once the taboo on the admission of blacks was broken with the employment of the very able Jackie Robinson, all barriers to the admission of blacks soon fell.)

In connection with the fact that free competition with members of so-called minority groups can entail a fall in the wage rates of the average member of the groups already established, most notably, white male workers, it should be realized that any such reductions in wage rates would take place as part of a process operating to raise the *real wages*—the actual standard of living—of the average member of *all* groups. For it would be accompanied by reductions in the prices of consumers' goods greater than any reduction in after-tax money incomes experienced by the average member of the groups already established. This conclusion is conclusively demonstrated in later chapters of this book.²⁴

Of course, none of the above developments can occur if they are stopped by the initiation of physical force. If, for example, the local Ku Klux Klan is able to burn down the factory of an employer who employs blacks instead of whites, because it knows it will go unpunished by the law; or if local government officials are capable of suddenly finding all kinds of violations of building, health, and safety codes on the part of such an employer, to the point of crippling his operations, then employers will not seek to take advantage of the lower wages of blacks, and thus the wages of blacks will not be raised to parity with those of whites of equal skill.

Although not motivated by racial prejudice, what is also capable of aborting the advance of blacks (and women), particularly at the higher levels of employment, is a system of taxation that takes away the greater part of the additional profits that might be made by defying custom and making the necessary innovations of bringing them into fields of employment in which they were previously not represented. Indeed, industries whose profits are limited by the government, such as public utilities, or whose output is purchased on a cost-plus basis, such as that of defense contractors, have no financial incentive whatever to make such innovations. And, of course, in an environment in which destructive government regulations can be unleashed at any time on virtually any business, or in which valuable government favors or outright government subsidies can be obtained—in an environment, therefore, in which it does not pay to have enemies, or to offend any significant group, or, as the saying goes, in which it does not pay “to rock the boat”—businessmen will not be very quick to make such controversial innovations in employment.²⁵ Ironically, such measures as equal-employment-opportunity laws directly rule out the very possibility of employing blacks or

women at lower wages for the same work as whites or men. They thus directly prevent businessmen from finding the employment of blacks or women in the higher positions to be unusually profitable—profitable enough to begin defying traditions and customs based on nothing more than empty stereotypes.

Later discussion will show the especially destructive effects of minimum-wage and prounion legislation on blacks, in aborting the very possibility of their gaining significant advancement.²⁶

The uniformity-of-profit principle implies that along with equal pay for equal work, capitalism operates to supply the members of all groups on equal terms in their capacity as consumers. As a demonstration of this fact, assume that blacks had to pay monthly rents just 5 percent higher than those of whites, while the landlord's costs were the same in both cases. This 5 percent premium would constitute a major addition to a landlord's profits. If a landlord's profit margin—his profit as a percentage of his rents—were normally 10 percent, a 5 percent addition to his rents would constitute a 50 percent addition to his profits. Even if his profit margin were initially as high as 25 percent, a 5 percent addition to his rents would constitute a 20 percent addition to his profits.

In response to such premium rates of profit, housing construction for blacks would be stepped up, and a larger proportion of existing housing would be rented to them. The effect of this increased supply of housing, of course, would be to reduce the rental premium paid by blacks. And because a mere 1 percent premium would mean significant extra profits in supplying blacks with housing, even a premium of this small size could not be maintained. Thus, blacks would pay no higher rents than whites, and obtain housing equal in quality to that obtained by whites.

Likewise, assume that merchants in black neighborhoods charged higher prices than the same goods would bring in other neighborhoods, while the merchants' costs of doing business were the same in both places. The higher prices in such a case would constitute a clear addition to profits. With higher profits to be made in black neighborhoods than white neighborhoods, merchants considering the location of new stores would choose the black neighborhoods. The influx of new stores, of course, would lower selling prices in the black neighborhoods; and the process would go on until the prices and the profits to be made in those neighborhoods were no higher than elsewhere. (Regrettably, today it is often the case that retail prices in black neighborhoods are substantially higher than for the same goods in white neighborhoods and, at the same time, merchants are

moving out of the black neighborhoods rather than moving in. This situation is the result of the existence of higher costs of operation in the black neighborhoods—caused by such phenomena as higher rates of burglary, pilferage, and arson—coupled with the inability in many cases to raise prices sufficiently to cover such higher costs, which inability results from the fact that prices are limited by competition with stores in surrounding areas. The obvious solution is to reduce the crime rate. Despite all the rhetoric to the contrary, the economic self-interest of the average black is allied with that of the merchants who supply him, not with that of the criminals who impoverish and destroy the merchants.)

Moreover, under *laissez-faire* capitalism racial segregation would disappear, even though it would be legally permissible on private property. It would disappear because it is fundamentally incompatible with the requirements of profit-making and because it is irrational.

The businessman seeking profit is vitally dependent on the patronage of customers. This dependency is expressed in such popular sayings as “the customer is king” and “the customer is always right.” Blacks are customers, and, as they rose economically, would be more and more important customers. It is absurd to believe that businessmen would want to turn customers away by denying them access to their premises or by humiliating them with such requirements as separate drinking fountains. The businessman’s desire for profit makes him put aside all such malice. It does not matter that he personally may not like blacks. All he has to like is their money. Competition with other businessmen for the patronage of blacks then does the rest.

It might be objected that despite the willingness of businessmen to abolish segregation when doing so is profitable, the attitudes of white customers might prevent such action from being profitable. For example, it would obviously not be profitable to gain five poor black customers and lose ten good white ones as a result of desegregating.

Cases such as this could exist, in places such as the deep South of previous generations. But they could exist only in an ever-diminishing sphere. Even in the deep South of the past, there were many whites who positively desired equal treatment for blacks, and many more who did not oppose it strongly enough to withdraw their patronage from a business which desegregated. As a result, in the absence of government intervention, and the threat of private violence sanctioned by local governments, there would have been many businessmen in the South who would have found that, while they might lose some white customers by desegregating, they would by no means lose all, and would gain more black customers

than they lost whites. This would have been certain to occur in areas where the population was relatively concentrated—that is, lived in cities or large towns—and in which the proportion of blacks was relatively high. In such areas, a businessman who desegregated would have been able to count on a relatively large black market to more than compensate him for his loss of white customers. For example, imagine a mass merchandiser, such as Sears, in a Southern town where there were two other such stores. If this store abolished segregation, it would certainly not have lost all of its white customers. Not that many Southern whites were so bigoted that they would have refused to shop there just because the store no longer humiliated blacks. Desegregating, however, would have enabled this store to gain a large number of black customers from the other two stores, for the blacks would have flocked to where they were treated as human beings. Desegregation would thus have been profitable for this store.

This case would have been repeated throughout the South. From practically the first day of freedom from government intervention and government sanctioned private coercion, there would have been voluntarily unsegregated stores, restaurants, hotels, and other establishments. The existence of these unsegregated establishments in their midst would then have acted to change the attitude even of those whites who had initially refused to deal with them. They would have seen with their own eyes that others were not contaminated by contact with blacks and that they would not be either. Thus, as time went on, fewer and fewer whites would have been prepared to withdraw their business from establishments which desegregated. The result would have been that businessmen would have had less and less to lose by desegregating; and the rising earning power, and thus growing buying power, of blacks would have given them more and more to gain. Finally, segregation would have come to be regarded as eccentric and then have ceased to exist altogether.

In this way, even such barriers as racially restrictive covenants in real estate would have been overcome. Property free of such restrictions, and therefore open to a wider market, would have become more valuable than property which carried them. Such covenants would have fallen into disuse and have been eliminated by voluntary consent.

Thus, even in areas such as the deep South, the extension of the economic freedom of capitalism to racial matters would have meant a significant measure of immediate integration, followed by an accelerating growth in integration. And it would all have been achieved voluntarily, in the pursuit of self-interest, in a spirit of mutual good will.²⁷

5. Prices and Costs of Production

In a free market the prices of products tend to be governed by their costs of production.

This principle follows directly from the uniformity-of-profit principle, and we have already glimpsed it in discussing the long-run consequences of repealing price controls. The uniformity-of-profit principle implies that the prices of products tend to equal their costs of production plus only as much profit as is required to afford the going rate of profit on the capital invested. If prices exceed costs by more than this amount of profit, then there is a tendency toward expanded production and lower prices (and possibly higher unit costs). If they fail to exceed costs by as much as this amount of profit, then there is a tendency toward reduced production and higher prices (and possibly lower unit costs). The stopping point is, as I say, where prices equal costs of production plus the amount of profit required to yield the going rate of profit on the capital invested.

Now there are two ways that cost of production governs prices. One way is indirectly—through variations in the supply of the good, as above. The other way is directly—through the decisions of the sellers of the good in setting their prices.

Let us consider first the cases in which the role of cost is indirect—for example, all or most agricultural commodities. In any given year, the price of wheat, or potatoes, or cotton, or whatever, is determined simply by supply and demand. Over a period of years, however, the price of such a good tends to gravitate about its cost of production. This is because whenever the price begins to exceed cost by more than what is required to afford the average rate of profit to the industry, additional capital will be invested, supply will be expanded, and the price and profit will decline. If the price fails to provide the average rate of profit to the industry, capital will be withdrawn, supply will be reduced, and the price and profit will be restored. What ties price to cost in such a case is variations in supply.

However, there is a vast category of cases in which the connection between price and cost is far more direct. This is the case of most manufactured or processed goods. In these cases, the sellers typically maintain inventories of their goods and have plant capacity available to produce more. In such a situation, a rise in demand, provided it is not too large, is met out of inventories, and before the inventory is exhausted, production is stepped up from plant capacity held in reserve. Similarly, when a fall in demand occurs, inventory is temporarily allowed to build up, and production is cut back. Provided the changes in demand are not of major proportions, there is little or no change in price. It can be observed, for

example, that the price of bread, automobiles, newspapers, restaurant meals, paper clips, and countless other goods does not change with every change in demand. A change in demand must be fairly substantial to raise or lower the price of these goods. In cases in which the demand changes are not too substantial, they are simply accompanied by corresponding changes in production, while the price of the product remains the same.

In cases of this kind, it is not correct to say that the price of the product is determined simply by supply and demand. On the contrary, the price of the product determines the quantity of the product the buyers buy, and the quantity that the buyers buy determines the quantity the sellers produce and sell.

The prices themselves in these cases are set by sellers on the basis of a consideration of costs of production. It is not that each seller sets his price on the basis of his own costs. But some seller in an industry—usually, the most efficient large firm and one that is in a position to expand its production significantly from existing capacity—sets its price on the basis of a consideration of costs, and the other firms are forced to match its price. The other firms cannot exceed its price, because it has the additional production capacity required to supply many of their customers if they should try to sell at higher prices. Nor, as a rule, can the other firms undercut its price, because it is the lowest-cost, most efficient producer, and sets its price accordingly.

The cost of production on the basis of which such a firm sets its price is not primarily its own cost of production, but the costs of production of its less efficient competitors or, if it has no current competitors, the costs of production of potential competitors. It sets its price in such a way as to prevent its competitors from earning too-high profits, because it does not want them to accumulate the capital that would enable them to become more efficient and to expand at its expense. Nor does it want to invite new firms into its field. It wants to avoid creating a situation in which it makes it possible for others to make inroads into its business, which, once started, might lead to its own downfall. It therefore tries to set its price in such a way as to prevent this, which means it tries to set its prices not very far above their costs—as a maximum. At the same time, of course, it strives to reduce its own costs of production even further, so as to be able to expand its own profits and to be able comfortably to meet any price reductions inaugurated by competitors that in the meanwhile may have grown more efficient. It is only when the demand for the product becomes so strong that it is not possible to meet it at a price determined in this way, that the price rises to permit high profits to all in the field.

In the case of manufactured and processed goods,

therefore, the direct determinant of price is cost of production.²⁸

However, as should already be clear from Chapter 5, if we examine costs of production, we find that they are reducible to two things: to the physical quantities of the means or factors of production employed to produce a good and to the prices of those factors of production.²⁹ For example, the cost of producing an automobile equals the quantity of each type of labor employed in turning out a car times the wage rates of that labor, plus the quantity of steel used times the price of that steel, and so on. Now the prices of these factors of production are themselves directly determined either by supply and demand or by cost of production. For example, the wage rates are determined by supply and demand, while the price of steel is determined by cost of production.³⁰ Now the costs of producing steel and all the other elements of an automobile whose prices are determined by cost are themselves resolvable in the same way as the cost of producing an automobile. That is, they in turn are based on prices directly determined by supply and demand and prices directly determined by cost of production.

It should be observed that as we keep pushing the matter back and back, the cumulative role of prices directly determined by supply and demand becomes greater and greater. In the case of our automobile, the production cost of an automobile ultimately depends on the wages of auto workers, the wages of steel workers, the wages of iron miners, and so on, all of which are determined by supply and demand. And, along the way, the prices of some of the materials, such as the copper and zinc the auto companies may have to buy, the raw rubber the tire manufacturers buy, the scrap metal the steel producers need—these prices, too, are directly determined by supply and demand. Ultimately, therefore, as far as it rests on prices, cost of production itself is determined entirely by supply and demand.

Consequently, when prices are determined by cost of production, what they are ultimately determined by is still supply and demand, but supply and demand operating in a wide context—that is, by supply and demand operating in the context of the labor market and in certain broad commodity markets, not in the relatively narrow market of the individual product itself.³¹

The analysis of cost of production into elements which are themselves determined by supply and demand brings us full circle. We began the analysis of price determination in Part B of Chapter 5 with a discussion of supply and demand, and now we must return to supply and demand, in order to explain prices determined on the basis of cost of production. For, as we have seen, insofar as cost of production rests on prices, those prices are ultimately determined by supply and demand. Thus, if

we want an ultimate explanation of prices determined by costs, we must explain prices determined by supply and demand. This will be our task, at a more advanced level than before, in the next part of this chapter, as we complete the presentation of the free market's laws of price determination.

PART B

ALLOCATION PRINCIPLES

1. The General Pricing of Goods and Services in Limited Supply

The determination of price by supply and demand applies to all goods and services whose supply is a given fact and therefore limited for a longer or shorter period of time to come. As we have seen, it also applies *indirectly* (via determining the prices that constitute their costs of production) to products whose supply can be immediately varied in response to changes in demand.

It is necessary to consider a kind of catalog of goods and services in limited supply, in order to understand concretely the range of application possessed by the principle of supply and demand.

The most important item in this list is, of course, human labor, which is always limited by the number of people able and willing to work. Furthermore, the labor of each person is limited by his need for rest and relaxation. And, as the general level of real wages—that is, the quantity of goods a worker can buy with his money wages—goes up, the fewer are the hours that people are prepared to work. This occurs because to the degree that people can earn a higher standard of living from any given number of hours of labor, their need for the additional real income that extra hours could provide is less intense. In addition to this, of course, the supply of skilled labor is always still further limited, and that of professional-level labor even more so; and, at any given time, the supply of labor in each occupation and each location is very narrowly limited.

After labor services come materials whose supply is temporarily limited, such as agricultural commodities between harvests. Housing and buildings of all kinds are in a state of temporarily limited supply, because considerable time is always required before their supply can be increased through new construction. Any material, any product whatever, is capable of being in limited supply temporarily, if the demand for it outruns the ability to supply it from existing facilities at a price based on cost of production.

Land sites are in the category of goods in limited supply on a long-run basis, insofar as there is anything

special or unique about them that makes them superior to other land, such as their superior location or superior fertility.³²

In a few cases, the products of such land sites are also in the category of goods in limited supply on a more or less permanent basis: for example, wines of a special flavor that can be produced only from grapes grown on a soil of a very limited extent, or caviar found in sturgeon beds located only in a few places.

Goods such as paintings and statues by old masters, first editions, rare coins, and so on, are in the category of goods in limited supply on an absolutely permanent basis, because their production is necessarily past.

Finally, all second-hand goods are in a state of limited supply.

The prices of all goods and services in limited supply are determined in an essentially similar way in a free market and have a similar significance. One basic determinant is *the quantity of money* in the economic system. As previously indicated, the quantity of money determines aggregate demand.³³ It can do this, of course, only in determining at the same time the demand for the various individual goods and services. We will not go too far wrong if we assume that once the economic system becomes adjusted to a change in the quantity of money, the effect of the change is to change the demand for everything more or less to the same degree. For example, in the long run, if the quantity of money doubles, and everything else remains the same (including such things as the rate at which the money supply increases and is expected to go on increasing), the demand for each individual good and service in the economic system should also tend to double. With a doubled quantity of money, we should expect that eventually the demand for shoes, baseballs, zinc, skilled and unskilled labor, and all other goods and services should all just about double. This means that, in the long run at least, we can regard the quantity of money as acting more or less equally on the price of everything.³⁴

The second major determinant of the prices of goods and services in limited supply is *the value judgments of the consumers with respect to the various goods and services on which they spend the quantity of money*. The value judgments of the consumers determine, in effect, how the aggregate demand that is made possible by any given quantity of money is distributed among the products of the various industries and among all the different goods and services in limited supply. The value judgments of the consumers determine, for example, how much is spent for shoes versus shirts, and indirectly, therefore, how much is spent for leather versus cloth, cowhides versus cotton, and grazing land versus cotton land; similarly for the labor services at each stage. In

determining the relative spending for all the different consumers' goods, each with its own requirements for labor of specific types, the consumers determine how much is spent in the economy as a whole for each type of labor in relation to every other type of labor, both in terms of specific occupations and in terms of wide groups of occupations, such as skilled labor versus unskilled labor. The same applies to all other goods and services in limited supply, such as diamonds versus wheat, real estate in New York City versus Des Moines, Iowa, and so on. In this way, the value judgments of the consumers ultimately determine the prices of all goods and services in limited supply in relation to one another. It is the value judgments of the consumers that ultimately determine how much more professional-level labor must be paid relative to skilled labor, and how much more skilled labor must be paid relative to unskilled labor.

In sum, the quantity of money determines the absolute height of the prices of goods and services in limited supply, and the value judgments of the consumers determine their relative heights. The value judgments of the consumers are, of course, judgments with respect to *marginal quantities*, and one may say that the relative prices of goods and services in limited supply are determined by their relative marginal utilities, or, in the case of factors of production, the relative marginal utilities of their final products to the consumers.³⁵

2. The Pricing and Distribution of Consumers' Goods in Limited Supply

For our purposes, the most important characteristic of the price of a good in limited supply is the fact that *in a free market it always tends to be set high enough to level down the quantity of the good demanded*—that is, the quantity of it that buyers are seeking to buy—to *equality with the limited supply of it that exists*.

For the sake of simplicity, consider the case of a rare wine, for example. It may be that, potentially, millions of people would enjoy drinking this wine and would be prepared to buy tens of millions of bottles of it every year. But because of the limitation of the special soil on which the necessary grapes can be grown, no more than, say, ten thousand bottles of the wine can be produced in an average year. What happens in this case is that the price of the wine rises to such a point that the great majority of potential buyers are simply eliminated from the market. They look at the high price and say to themselves, "This wine is simply too expensive for me, however delicious it may taste." In fact, in the knowledge that this would be their decision, the very existence of such a wine would probably never even be called to the attention of the great majority of people. As for those who do buy the

wine, the high price probably makes almost all of them restrict the amount of it that they consume. At fifty dollars a bottle, say, even millionaire wine lovers probably drink it much less often than they would at, say, ten dollars a bottle.

The case of apartment rentals is essentially the same. In a free market, rents go high enough to level down the quantity of rental space demanded to, or somewhat below, equality with the limited supply of it that exists. The only difference is that in an economy like that of the United States, no one need be excluded from the rental market entirely. Everyone is always able to afford to rent *some* space, even if it is only half of a room he must share with someone else.³⁶

Always, a free-market price acts to level the quantity demanded of any good or service in limited supply down to equality with the supply that exists.

This characteristic of a free-market price has a major implication. *It implies that shortages cannot exist in a free market, even in cases of the most severely limited supply.* That is because, however limited the supply may be, a free-market price always rises high enough to level down the quantity demanded to equality with the supply available. In a free market, limited supplies do not cause shortages, but high prices. At the high price, there is no shortage.

In order further to prove this point, let us take an extreme example—one that is very unfair to the free market, namely, the case of the gasoline shortage of 1973–74. In a variety of ways, the government was responsible for vastly reduced supplies of gasoline, especially in the Northeast. Let us start with these artificially low supplies of gasoline and imagine that at that point the government had simply repealed its price controls on gasoline.

Whoever went through the experience should think back to the sight of service stations faced with multi-block-long lines of cars waiting for gasoline. Let us imagine a service station that has 1,000 gallons of gasoline in its own tanks and is confronted with a line of cars whose drivers are seeking 2,000 gallons of gasoline for their tanks. This is a case of 1,000 gallons of gasoline available, 2,000 gallons demanded. Even in this case, a free market would have equalized the quantity demanded with the supply available. If the owner of the gas station had been free to set his own price, he would have set a price high enough to make those drivers reduce the quantity they demanded by 1,000 gallons. Such a price undoubtedly existed. If the reader doubts this, he should imagine the gas station owner simply auctioning his gasoline off to the highest bidders. As the price at the auction rose, more and more bidders would have restricted the quantities they bid for, and some would have

dropped out of the bidding altogether. At some point, the quantity of gasoline demanded would have been cut back to equality with the 1,000 gallons available. It makes no difference, of course, if instead of conducting an auction, the service station owner had simply set his price where such an auction would have set it. In either case, people who previously were prepared to buy 2,000 gallons of gasoline would have found that they could not afford more than 1,000 gallons and would have limited their purchases accordingly.

In fact, things would have gone further than this. A service station owner not restricted by price controls would have considered not only the demand of the drivers of the cars presently in line, but also the demand of all the drivers of the cars that might have shown up later in the day, or the next day, or any time before his next deliveries were to arrive. He would not have been willing to sell gasoline to someone presently in line if he expected that someone else would show up later willing to pay more. The price he set, in other words, would have corresponded to the price set in an auction market that extended over time and represented future bidders as well as present bidders.

The effect of the owner's pricing gasoline in this way would have been not only further to reduce the quantity demanded on the part of those presently in line, thereby reducing the waiting line further, *but actually to make gasoline available at all times at his service station.* Since all other service station owners would also have been pricing gasoline in the same way, motorists would soon have realized that gasoline was in fact available whenever they wished it and in whatever quantity they wished it—provided they were willing to pay the price. There would have been no shortage and motorists would have known that they did not have to fear a shortage; they would have ceased to be afraid to drive with less than a full tank of gasoline. (It should be realized that this is largely a description of what actually happened later on. Shortages ended in the spring of 1974 because the controls on oil prices were substantially relaxed, and totally eliminated as far as imported oil was concerned.)

Of course, in the case of a good like gasoline, a rise in price to the free-market level not only restricts the quantity demanded, and eliminates the need to hoard, but also pulls in supplies from other geographical areas. As we will see, it also causes oil refineries to step up the production of gasoline at the expense of other petroleum products, if necessary. And, in the long run, it increases the total production of oil products. In these ways, a free market not only balances the demand and supply of gasoline, but does so at the point of large and, indeed, continuously growing supplies.

However, the crucial point here is that even in the case

of goods in strictly limited supply, there are no shortages, no waiting lines, in a free market. Whoever has the price is always able to buy as and when he wishes, and as much as he wishes.

There is a further very important point that follows from our discussion. This is the fact that in the context of limited supplies, it is not only to the self-interest of the sellers that prices rise when conditions make it necessary, but, no less, to the self-interest of the *buyers*. It is simply not true, as most people seem to believe, that the interests of buyers are always served by low prices. On the contrary, *it is to the self-interest of buyers of goods in limited supply that prices be high enough to exclude their competitors from the market.*

To grasp this point in the clearest possible way, imagine an art auction, with two bidders for the same painting. One of them is willing to go as high as \$1,000; the other, as high as \$2,000. The man whose limit is \$2,000 would certainly like to pay as little as necessary. He would be glad to pay just \$100, or less, if he could. But given the fact that someone else at the auction is prepared to bid up to \$1,000, it would be very foolish for this man to insist on paying any preconceived figure below \$1,000. If he arbitrarily insisted on bidding any amount below \$1,000, the effect of his action would simply be to allow the painting to go to his rival. If he bid exactly \$1,000, and refused to bid any more, he would make it a matter of accident to whom the painting went—if the other bidder bid the \$1,000 first, it would probably go to that other bidder. In either case, by refusing to outbid the other bidder, he would prevent himself from getting the painting he wants and which he really values above the other bidder's maximum of \$1,000 for the painting.

There is absolutely no difference as far as this man is concerned if, instead of his having to appear personally at an auction and outbid his rivals, the art dealer who possesses the painting anticipates the strength of his bid, and simply sets a price on the painting in his gallery that is high enough to deter other potential buyers and thus to reserve it for him. From the standpoint of the rightly understood self-interests of this man, it is a positively good thing that the art dealer asks more than \$1,000, because if he did not, someone else would buy the painting and it would be gone by the time our man got around to trying to buy it.

The only difference between the cases of the art auction and the art dealer and that of all other commodities in limited supply is simply one of size. Instead of it being a unique painting that is put up for auction or for sale and which is of interest to a relatively small number of bidders or potential buyers, it is more common to have millions of units of the same good offered in the market

and sought after by large numbers of bidders or potential buyers. Just as in the case of the painting, in all these cases, too, the fact that a price is high enough to level down the quantity of the good demanded to equality with the limited supply of it that exists is very much to the interest of all those buyers who are willing and able to pay that price. That price is their means of eliminating the competition for the good from other bidders or potential buyers not willing to pay as much. It is their means of being able to secure the good for themselves. In our example of the wine, for instance, the price of fifty dollars a bottle—if that is the price necessary to level the quantity demanded down to equality with the supply available—is in the interest of everyone who values the wine at or above fifty dollars. If the price were any lower, the wine would be within reach of other potential buyers, who did not value it so highly, and it would, therefore, to that extent, not be available to those who did value it so highly. In the same way, whatever price of a square foot of rental space, or any other good, is required to level the quantity demanded down to equality with the supply available, that price is to the interest of all those who value that space or that good at that price or any higher price. If the price were any lower, they would simply lose their ability to secure the good for themselves—the good would be bought up by those not able or willing to pay as much, and to that extent it would be unavailable to those who did value it sufficiently.

There are two possible misunderstandings of what I am saying that I want to anticipate and answer before going any further.

First, I want to stress that the ability to outbid others for the supply, or part of the supply, of a good is by no means the exclusive prerogative of the rich. The fact is that absolutely everyone exercises this prerogative to the extent that he earns an income or has any money to spend at all. Even the very poorest people outbid others, and the others whom they outbid can include people who are far wealthier than themselves. Of course, this is not true in a case such as our example of the rare wine, where the entire supply is obviously consumed by those who are quite well-to-do.

But it is true in a case such as rental space, or housing in general, where everyone succeeds in obtaining some part of the supply. In a case of this kind, a wealthier family will obtain a larger share of the supply than a poorer family, but what stops it from obtaining a still larger share is the fact that the poorer family outbids it for part of the supply. For example, a wealthier family may rent an eight-room apartment, while a poorer family rents only a four-room apartment. The reason that the wealthier family does not rent a nine-room apartment is

the fact that the poorer family is able and willing to pay more for its fourth room than the wealthier family is able and willing to pay for a ninth room.

This competition, of course, does not take place at an actual auction, but the result is exactly the same as if it did. If, for example, apartments are renting at some given figure per room, such as \$300 a month, and the poorer family decides it can afford a four-room apartment, while the wealthier family decides it cannot afford a nine-room apartment, the implication is that the poorer family values a fourth room above \$300, while the wealthier family values a ninth room below \$300. In effect, the poorer family outbids the wealthier family for the marginal room. If this poorer family wants to be sure of obtaining its four rooms, it is just as important to it that rents be high enough to level the quantity of space demanded down to equality with the supply available, as it is to the richer family.

If the price were any lower than the necessary equilibrium price, then while some poorer families might be able to afford a fifth room, wealthier families would just as often be able to afford a ninth room. And as often as poorer families succeeded in grabbing off a fifth room at the expense of a wealthier family's eighth room, a wealthier family would succeed in grabbing off a ninth room at the expense of a poorer family's fourth room. The same results apply to any good that is universally consumed: an artificially low price permits the "rich" to expand their consumption at the expense of the "poor" just as often as it permits the poor to expand their consumption at the expense of the rich.

Thus, the setting of prices at levels high enough to achieve equilibrium between the quantity demanded and the supply available is to the rational self-interest of everyone, irrespective of his income. Moreover, a harmony of interests exists in a free market even in those cases in which the price totally excludes some people from the market for particular goods. It exists on a remoter plane. For example, the price of Rembrandt paintings excludes the author of this book from the market for those paintings entirely and without question. Nevertheless, it is to my self-interest that if someone must be excluded, it be me, and not an industrial tycoon. For if his vastly greater contribution to production did not enable him to live at a better level than I do, I would be in serious trouble. To put this another way, if an industrial tycoon can have his art collection and other super-luxuries, then I can have all the food I want, a house, an automobile, and so on, and more and better all the time. If I were to be able to compete on equal terms with him for the super-luxuries, he would have no motive to conduct production in such a way that I am assured of all the necessities and lesser luxuries.

In order to avoid a second possible misunderstanding about the interest buyers have in prices being sufficiently high, I want to stress that I am *not* saying that people should simply welcome higher prices and be glad to pay them. Obviously, rising prices impose major hardships on large numbers of people, and they cannot simply look on stoically and be glad of their ability to pay those prices. However, there are two separate things here that must be very carefully distinguished, namely, the fact of the rise in prices and the cause of the rise in prices.

Our example of the art auction will serve to make this distinction clear. Assume that the losing bidder, whose maximum bid was previously \$1,000, is now placed in a position in which he is able to bid as high as \$1,500. In order to outbid him, our man will now have to bid above \$1,500, whereas before he only had to bid above \$1,000. Obviously, this is not a pleasant development for our man. But nevertheless it is still to his interest to bid a price that is sufficiently high to secure him the painting. Our man should, indeed, still value the opportunity to outbid his rival. His sorrow should be directed only at that which now makes it more difficult for him to do so.

In the same way, even in periods of rising prices people should, indeed, still value the opportunity to outbid their rivals and the fact that sellers set prices high enough to achieve this objective for them. Their anger should be directed only at that which makes it more and more difficult for them to accomplish this overbidding. What they should be angry about is not the existence of a market economy and the way the market economy works *but at the presence in the market of a vast gang of dishonest bidders and dishonest buyers*, a gang that bids and spends dollars created out of thin air in competition with their earned dollars. As later discussion will show, the source of these dollars created out of thin air is none other than the government. And the dishonest gang consists of it and of everyone else who demands and receives such fiat money.³⁷

In other words, it is inflation and the pressure-group demands for inflation that the victims of rising prices should denounce, not the market economy or the opportunity it affords them for outbidding their rivals. It is the entry of newly created money into the economy that they should seek to stop, not the registry of that newly created money in the form of higher prices. Instead of, in effect, calling for the closing of the market, they should simply call for an end to the government's inflation of the money supply, and thus for the establishment of a *fully free* market—a market free of this as well as the government's imposition of price controls.

On the basis of the way their prices are determined, the distribution of consumers' goods in limited supply—

in the sense of who actually ends up with them—always tends to take place in a free market in accordance with two criteria: the relative wealth and income of the various potential buyers and the relative intensity of their need or desire for the good in question. The wealthier a buyer is, the more of any good he can afford to buy—obviously. But wealth is not the sole criterion of distribution. Where two buyers possess the same wealth, the one who needs or desires a good more intensely will be willing to devote a larger proportion of his wealth to its purchase, and he will therefore be able to outcompete an equally wealthy buyer who values the good less intensely. And, of course, in many cases a buyer who possesses a sufficiently strong desire will be able to outcompete a wealthier buyer, sometimes even a substantially wealthier buyer. In our example of the wine, for instance, a wine connoisseur of relatively modest means might very well be willing to pay prices that a millionaire would not. Or, because of their relative preferences, some poorer families might outcompete some wealthier families not just for a marginal room, but for an equal-size apartment by devoting a sufficient proportion of their income to rent.

In a free market, therefore, consumers' goods in limited supply are distributed in accordance with purchasing power directed by needs and desires, or, equivalently, in accordance with needs and desires backed by purchasing power. Everyone consumes these goods in accordance with a combination of his means and his needs and desires.

3. The Pricing and Distribution of Factors of Production in Limited Supply

All that we have learned about the prices of consumers' goods in limited supply applies to the prices of factors of production in limited supply, that is, to the prices of materials, labor, machinery, and anything else that is bought for business purposes and that is in limited supply.

The price of a factor of production in limited supply is also determined in such a way that the quantity of it demanded is levelled down to equality with the limited supply of it that exists, just like a consumers' good in limited supply. What pushes the price to the necessary height is, once again, a combination of the self-interests of the sellers and the buyers. The immediate buyers, directly concerned, are, of course, businessmen. Businessmen desire a factor of production not for the satisfaction of their own personal needs or wants, but in order to secure the means of producing goods for profit. Nevertheless, it is just as much against the interests of businessmen to try to pay too little for a factor of production as it is for a consumer to try to pay too little for something

he buys. Like a consumer, a businessman must be willing to pay prices that are high enough to secure him the things he wants. This means that he must be willing to pay prices that outbid what other businessmen are prepared to offer for the same part of the supply. (It follows that the doctrine that self-interest drives employers arbitrarily to pay subsistence wages is as absurd as the belief that self-interest drives the bidder at an art auction to offer scrap-paper prices for a valuable painting. Employers who would arbitrarily decide to pay too-low wages would simply enable other employers to hire away their labor. The employer who wants labor must be willing to pay wages that are high enough to make that labor too expensive for all its other potential employers.³⁸)

The only complication that is introduced by the price of a factor of production in limited supply is that it does double duty, so to speak. It not only levels down the quantity of the factor that is demanded to equality with the supply available, but, indirectly, the quantity of all the various products of the factor as well.

Let us consider first a simple case, such as cigarette tobacco, whose only product is cigarettes. The price of cigarette tobacco not only levels down the quantity of cigarette tobacco that is demanded, but, as a major part of the cost of producing cigarettes, it carries through to the price of cigarettes and also levels down the quantity of *cigarettes* demanded. The price of cigarette tobacco thus adjusts the demand for cigarettes to the supply of cigarette tobacco. Observe just how this happens. As the price of cigarette tobacco rises, the cost of producing cigarettes rises, which, in turn, raises their price. As the price of cigarettes rises, the quantity of cigarettes demanded falls. In fact, it is this fall in the quantity demanded of cigarettes, as their price rises, that necessitates a fall in the quantity demanded of cigarette tobacco, as its price rises. As the price of cigarette tobacco rises, businessmen purchase less of it because they know that they cannot sell as many cigarettes at the higher prices that are necessary to cover the resulting higher costs of production. In this way, therefore, the price of cigarette tobacco levels down the quantity demanded both of cigarettes as well as cigarette tobacco to equality with the supply of cigarette tobacco available.

Nothing is changed if we now consider the somewhat more complicated case of wheat or any other factor of production that has a variety of products, such as skilled labor. As the price of wheat rises, the cost of production and prices of all products made from wheat—such as bread, crackers, macaroni, whiskey, and wheat-fed cattle and chickens—also rise. The rise in the prices of wheat products reduces the quantity of the various wheat products demanded, and this reduces the quantity demanded of wheat. Again, as the price of wheat rises, businessmen

cut back their purchases in anticipation of the fact that they will not be able to sell as many wheat products at the higher selling prices necessary to cover the higher cost of wheat. In this way, therefore, through its effect on the cost of production and the selling prices of all the various wheat products, the price of wheat equalizes not just the quantity of wheat demanded, but also the quantity demanded of all wheat products as a group, with the supply of wheat available.

There is a further important similarity between what is accomplished by the price of a factor of production in limited supply and the price of a consumers' good in limited supply. If we look at the whole range of products of such a factor as forming a single group, we can observe the same essential principle of distribution with respect to the factor that we previously observed with respect to a consumers' good in limited supply. Namely, the benefit of the factor, as conveyed by its various products, is distributed to the various individual consumers in accordance with their relative purchasing power and in accordance with their relative desire for products of that type. For example, the benefit of the supply of wheat is distributed to the ultimate consumers in accordance with a combination of their relative wealth and relative preferences for products made of wheat. Other things being equal, richer buyers obtain the benefit of more of the supply of wheat than poorer buyers. Not that richer buyers eat more bread—they probably eat less of it—but they eat more meat, which requires the use of far more wheat to make possible its production pound for pound (in the feeding of cattle) than does bread. In the same way, a buyer with a relatively strong preference for wheat products, such as a buyer who especially likes steak and scotch, is able to obtain a larger share of the benefit of the wheat supply than a buyer of equal wealth who values these things less.

The benefit of the supply of crude oil, skilled and unskilled labor, and all other factors of production in limited supply is distributed to the ultimate consumers in just the same way.

Thus far, it is evident that the prices of factors of production in limited supply have the same characteristics and the same significance as the prices of consumers' goods in limited supply. The great difference between them pertains to the fact that there is an added dimension to the distribution of the factors of production. Not only is the benefit of a factor of production distributed to different persons, in accordance with their relative wealth and relative preferences, but the factor itself must be distributed to *different concrete uses in production*. Its benefit goes to the persons only by means of those specific uses. For example, consumers do not buy the benefit of wheat or skilled labor as such, but the various

specific products of wheat or skilled labor. The supply of the factor must be distributed among its various specific products—in order to produce them.

This distribution of a factor of production among its various products is the result of a further process of mutual bidding and competition among the consumers. Only this time, it is not merely one consumer bidding against another consumer, *but the different needs, desires, or purposes of one and the same individual consumers bidding against each other, as well*. For instance, there is a competition for wheat between its use for baking bread, its use for making crackers, its use for making whiskey, feeding meat animals, and so on. There is a competition for crude oil between its use for making gasoline, its use for making heating oil, and so on. And there is a competition for the labor of each ability group among all of its various possible employments. Since the same individual consumers consume most or all of the various products of these factors of production, the competition is, as I say, ultimately largely one between the competing needs, desires, or purposes of the same individuals.

In order to grasp the nature and the importance of this competition, let us consider the question of why just so many bushels of wheat—to continue with that example—are devoted to each of its specific uses. Why aren't a million bushels, say, withdrawn from making crackers and added on to baking bread? The reason this does not occur is that the consumers of the quantity of crackers requiring the million bushels in question are perfectly willing and able to pay a price for the crackers that makes it profitable to cracker manufacturers to produce them at the current price of wheat. The consumers of the crackers, in other words, are willing to allow the producers of the crackers to pay the present price of wheat. But suppose that a million bushels of wheat were used to produce additional loaves of bread. In order to find customers for the additional bread, its price would have to be reduced. In fact, in a country like the United States, where, as a rule, even the very poorest people can already buy all the bread they desire to eat, the price would probably have to be cut so drastically as to induce people to feed the extra bread to pigeons. Conceivably, the extra bread might not be saleable at any price. In any case, it is clear that the bakers of bread would not be able to buy any additional wheat except at a lower price of wheat. And that means that the bread industry, in effect, bids less for the million bushels of wheat in question than the cracker industry. The cracker industry gets the wheat by outbidding the bread industry. And this happens because ultimately the consumers of crackers are outbidding the consumers of bread for the benefit of that wheat.

For the same reasons, the reverse situation does not

occur either—that is, a million bushels of wheat are not withdrawn from the bread industry and added on to the cracker industry. For the consumers of the present quantity of bread are willing to pay prices for that quantity that allow the bread industry to be profitable at the present price of wheat. But the consumers of crackers would only be willing to buy a larger quantity of crackers at a lower price. In order for crackers to be profitable at a lower price, the price of wheat would have to be lower. As a result, the only way the cracker industry could buy an additional quantity of wheat would be at a lower price of wheat than the bread industry is willing to pay for it. Thus, the bread industry outbids the cracker industry for this particular quantity of wheat. Again, ultimately it is the consumers of the one product outbidding the consumers of the other product for the benefit of the quantity of wheat in question. And since it is the same people who consume both products, it is really one kind of need, desire, or purpose of the same individuals outcompeting another.

In exactly the same way, any other such transfer of wheat from one use to another is prevented by the fact that in its changed employment the quantity of wheat in question could only be employed profitably at a lower price than in its present employment. In other words, the present employments outbid the potential changed employments, and thus they get the wheat. And the reason they outbid them is because of the fact that the ultimate consumers are willing to allow more for the use of wheat in its present employments than in its changed employments.

In this way, the distribution of wheat to its various uses is determined by a process of competition among those uses, which in turn reflects a process of competition among the needs, desires, and purposes of one and the same individual consumers.

We can substitute any factor of production for wheat, and the results will be the same. If we ask why a million man-hours of unskilled labor are not withdrawn from one industry and added on to another, the answer again is that the consumers are willing to pay product prices in its present employments that enable businessmen to employ that labor profitably at its going wage rate; if the labor were shifted, however, the consumers would only buy the resulting products at prices that would require lower wage rates for their production to be profitable. These products, therefore, are unable to compete for the necessary labor. They are unable because of the choices and value judgments of the consumers, which enable the existing employments to outbid them.

A principle which emerges from our discussion is that *in a free market a factor of production in limited supply always tends to be distributed to its most important employments, as determined by the value judgments of the consumers themselves.* In our example of the distri-

bution of wheat, it was more important for the million bushels to be employed in producing crackers that people wanted—as demonstrated by their willingness to pay for them—than additional bread that people did not want or wanted less. It was more important for a million bushels to be retained in producing bread that was desired than to be added on to producing crackers that were less strongly desired—as manifested, this time, in the willingness of consumers to allow more for wheat used to produce bread than for wheat used to produce additional crackers.

It is this way in every case. A factor of production in limited supply is employed in those uses that can afford to pay the highest prices for it. And that is determined by the willingness of the consumers to pay prices for the resulting final products. Every factor of production in limited supply is distributed to those employments where the consumers are willing to allow the most for it in the prices of the goods they buy. That is, it is distributed to those employments which the consumers regard as the most important to their own well-being.

It must be stressed that the concept “the most important employments of a factor of production” is *a variable range* that expands or contracts with the supply of the factor of production available. What it means is the most important employments *for which the supply of the factor suffices*.³⁹ For example, if the supply of the factor is extremely limited, the most important employments for which the supply suffices might be as important as life itself. If the supply is very great, the most important employments can extend downward to include many luxury uses. The case of wheat again provides a good example. In a country like India, or medieval France, devoting wheat to its most important employments means, essentially, producing as much bread as possible to ward off starvation. In a country like the present-day United States, devoting wheat to its most important employments ranges downward through totally satisfying the desire for products such as bread and pasta, heavily satisfying the desire for such things as cakes and cookies made from wheat, substantially satisfying the desire for alcoholic beverages made from wheat, and partly satisfying the desire for wheat-fed meat.

A second major principle follows from this discussion. Namely, the price of every factor of production in limited supply, and thus the prices of all of its various products, is determined by the importance attached to the *least important of the employments for which its supply suffices*; that is, by the importance attached to its *marginal* employments. In our example of wheat, for instance, the price of wheat in the present-day United States is determined by the importance attached to the use of wheat in feeding meat animals—its marginal employment in the context of our economy. This results

from the fact that the price of wheat has to be low enough to permit its use to be profitable in *all* of its employments. If it is to be used in feeding meat animals, its price has to be low enough to make that use profitable at prices consumers are willing to pay for wheat-fed meat. However, there is only one uniform price of wheat in the same market at the same time. As a result, the bread industry pays no more for wheat than the cattle-raising industry. And because the price of bread is determined by its cost of production, the price of bread in the United States is actually determined not by its own importance, which may be as great as the stilling of hunger, but by the relatively low importance attaching to the use of wheat in producing meat.

Or, to take another example, the price of surgical instruments, on which countless lives may depend, is not determined by the importance of the needs they serve directly. It is not even determined by the importance attached to the marginal employments of iron and steel, but by the importance attached to the marginal employments of the ability groups of the labor that produces iron, steel, and surgical instruments. For the price of the surgical instruments is determined by their cost of production. And the wage rates which constitute that cost are low enough to make the employment of the different ability groups of labor profitable in their marginal employments. To put it another way, the price even of surgical instruments is no higher in relation to the wages of the ability groups of labor employed to produce them than the marginal products of such labor, which may be a quantity of razor blades or even magazines or chocolate bars or who knows what.

To summarize our discussion of factors of production in limited supply, we have seen that all the principles apply that we developed in relation to consumers' goods in limited supply, plus two others: First, that factors are distributed to their most important employments through a process of the different needs, desires, and purposes of the same individual consumers bidding against one another. And second, that the prices of the factors are determined with respect to the *least important* among the employments for which their supply suffices. Determination of price by cost, we have seen, therefore, ultimately means determination with respect to the consumers' value judgments concerning the *marginal products* of factors of production.⁴⁰

4. The Free Market's Efficiency in Responding to Economic Change

On the basis of the way their prices are determined, every change in the demand or supply of a factor of

production in a free market tends to be dealt with in the most rational and efficient manner possible—that is, in a way that maximizes gains and minimizes losses.

To understand why this is so, imagine that the demand for one product in the economic system rises, while the demand for another product falls. For the sake of simplicity, assume for the moment that the two products are produced with the same factors of production. Washing machines and refrigerators are a good illustration of such products, because both of them require just about the same overall proportions of skilled and unskilled labor in their production, use largely the same materials, and can probably be produced in the very same factories without great difficulty. If the demand for one of these products increases while the demand for the other decreases, there will probably be little or no change at all in the demand for factors of production that cannot be matched by an immediate corresponding shift in their supply. Essentially, all that occurs in this case is that more of the same kinds of factors are employed in one capacity, and less in another. In accordance with a change in consumer demand, the production of the one item is expanded while the production of the other item is contracted. In this case, there is obviously no tendency toward a change in the prices of the factors of production.

But now let us consider a more complicated case, which will bring out an important new principle of the free market. Assume that a change in fashion occurs which dictates that the average person own one extra wristwatch, and which, at the same time, encourages him or her to own one less suit or dress. I choose this example because the labor used to produce clothes cannot be transferred to the production of watches, due to the enormous skill differences involved. Here, therefore, we have a case of changes in the demand for factors of production that cannot be matched by offsetting shifts in their supply. Let us see what happens in such a case in a free market.⁴¹

The wage rate of watchmakers and the cost of production and price of watches, of course, will rise; while the wage rate of garment workers and the cost of production and price of clothing will fall. However, the effects will not be confined to these initial areas of impact. A rise in the wages of watchmakers will begin to attract other workers into the field, say, some workers who would have gone into instrument making, optics, jewelry making, and so forth—that is, whatever fields employ labor of a kind that can be used to make watches. A fall in the wage rates of garment workers, on the other hand, will begin to push some of these workers out of that field and into other fields. As a result, a tendency develops toward widening and diffusing the initial impact of the change in demand.

As workers leave fields such as instrument making and optics to go into watchmaking, the wage rates and thus the production costs and product prices in these fields will begin to rise. Thus, the rise in demand for watches will raise not only the cost and price of watches, but also the cost and price of instruments, optical goods, and so forth—all products that use the same kind of labor as watchmaking. Conversely, as workers leave the garment industry and begin to enter other fields for which they possess the necessary skills, the wage rates, production costs, and product prices in those fields will begin to decline.

The question we want to ask is: what *principle* determines which industries among those that employ the same kind of labor as watchmaking actually release additional labor for watchmaking, and to what extent? And which industries among those potentially capable of absorbing the labor released from the garment industry actually absorb it, and to what extent? To arrive at the answer, we must realize that at the higher prices of the various goods that use the same kind of labor as watches, the consumers will reduce their purchases of those goods. It is these decisions of the consumers to restrict their purchases, that determine which of the industries release labor for watchmaking and to what extent. For example, if the consumers decide to go on buying an unchanged quantity of optical goods at their higher price, but a reduced quantity of jewelry and various instruments, none of the labor will come from the optical goods industry, and all of it will come from the jewelry and instrument industries. Obviously, the labor will come from these various industries in accordance with whatever proportions the consumers decide to curtail their purchases of the various products at their respectively higher prices.

Clearly, what occurs in this case is an indirect bidding for the use of labor between the buyers of wristwatches and the buyers of all other products employing the same kind of labor. The buyers of wristwatches cause a bidding up of the price of the wider category of labor that produces both wristwatches and all the other products I have named. As a consequence of this intensified bidding for labor, the buyers of these other products—jewelry, instruments, optical goods, and so forth—are confronted with higher product prices and so must restrict their purchases. To the degree that they restrict their purchases, they release labor to the watch industry and make possible its expansion.

Now to the extent that the consumers are rational, the products whose purchase they discontinue at the higher prices will be the *least important* among the ones they previously purchased. That is, the consumers will discontinue their previously *marginal purchases*. For each

consumer who buys these various products will cut back his purchases in the way that hurts him least in his context and in his judgment. Thus, if he needs eyeglasses, he will certainly go on buying a pair of eyeglasses, but perhaps forgo the purchase of a telescope for his hobby, say. If he was previously in a position to buy several pairs of eyeglasses and a telescope and some jewelry, then, when he is confronted with higher prices for all of them, he may decide to go ahead with the telescope but cut back on an extra pair of sunglasses and some jewelry. The effect on the quantities demanded of these goods in the whole economy is, of course, simply the aggregate of all such individual decisions. In this way, it can be seen that in a free economy the labor released for watchmaking will come from its previously marginal employments—that is, from the employments where all the various individual consumers in the market judge they can best spare it.

By the same token, the labor released from the garment industry will be absorbed in those employments which are the most important of the employments for which the supply of that type of labor did not previously suffice; that is, it will be absorbed in the most important of its previously submarginal employments. This conclusion follows from the fact that the workers released will be seeking to earn the highest incomes they can and that these incomes will be found in producing those goods for which the consumers are willing to allow the highest prices over and above the allowance for the other costs entailed in producing them. The displaced garment workers will enter whatever fields can absorb them with the least fall in wage rates. These are the fields whose products the consumers are willing to buy in additional quantities at the least fall in prices. They offer the displaced garment workers the highest wages now available to them. I have not attempted to enumerate these other employments because the skills involved are so common that the labor released would probably be absorbed to some degree in a vast number of industries. For example, some of the former garment workers might end up as office workers, taxi drivers, metal workers, or who knows what.

Everything we have seen concerning the source of labor for additional watches applies in principle to the source of any factor of production in limited supply for an expansion of the production of any good. Always, the process is one of an intensified bidding for the factor by businessmen acting as agents of the consumers of one or more of its particular products against businessmen acting as agents of the consumers of its other products. This bidding drives up the price of the factor, the costs of using it in production, and the prices of all of its various products. Supplies of the factor are always released, in accordance with the choices of the consumers, from the

production of its previously marginal products—from the products where the consumers decide they can best spare it. In the same way, everything we have seen concerning the absorption of labor released from the garment industry applies to the absorption of any factor in limited supply released from any industry. Always, the factor is absorbed in the most important of its employments previously unprovided for, in accordance with the judgment of the consumers, as manifested in what they are willing to pay the most for.

The identical reasoning that we have applied to changes in the demand for a factor of production in limited supply applies to changes in the supply of such a factor. If the overall supply of a factor should increase, the addition goes to provide for the most important of the employments of the factor previously unprovided for. For example, an increase in the supply of wheat in the present-day United States would be used to expand the production of such things as wheat-fed meat and aged whiskey. If the supply of a factor should decrease, the reduction is taken out on the least important of the employments previously provided for. In the case of wheat in the context of the present-day United States, this would mean a reduction in the production of such things as wheat-fed meat and aged whiskey. In other words, an increase in the supply of a factor goes to the most important of its previously submarginal employments; a decrease is taken out on its previously marginal employments.

The principle that emerges from this discussion is that *in a free market if a factor of production is in reduced demand or additional supply, the portion of it that becomes newly available is channelled to the most important of its previously submarginal uses; if the factor of production is in additional demand or reduced supply, the portion of it that is no longer available is taken from the least important of its previous uses, that is, from its previously marginal uses.* In other words, as stated, every change in the demand or supply of a factor of production in a free market is dealt with in a way that maximizes gains and minimizes losses; which is to say, it is dealt with in the most rational and efficient manner possible.

A Rational Response to the Arab Oil Embargo

The above principle has major application to such economic disruptions and pretenses for price controls as the Arab oil embargo. It enables us to understand in yet another respect how a free market would have minimized the impact of any reduction in the supply of oil that the Arabs might have been able to impose on us, and would minimize any other such disruption that might occur in the future.

If we had had a free market, the price of crude oil and the production costs and prices of all oil products would

have risen during the embargo. The consumers would have decided where the reduction in the use of crude oil was to be effected and to what degree, by the extent to which they cut back on their purchases of the various oil products at the higher prices. Where the use of an oil product was important, consumers would have paid the higher price, and oil would have continued to be used for that purpose. Only where the use of an oil product was not worth its higher price, would the use of oil have been cut back or discontinued. For example, consumers would have paid a higher price for the gasoline required to drive to work and for the heating oil required to keep them warm. They would not have been as ready to pay higher prices for the gasoline required for extra shopping trips or for heating oil to keep their garages warm.

The crucial point is that in a free market the more important employments of oil would have outbid the less important ones, and the reduction in the supply of oil would have been taken out exclusively at the expense of the *marginal* employments of oil—that is, at the expense of the least important employments for which the previously larger supply of oil had sufficed.

But, of course, we did not have a free market. We had price controls. Price controls prevented the more important employments of crude oil from outbidding the less important employments. They prevented the most vital and urgent needs for oil from outbidding the most marginal. For example, during the oil shortage 1973–74 one could read stories in the newspapers about truck drivers not being willing to deliver food supplies to southern Florida for fear of being unable to obtain fuel for the return trip up the length of the Florida peninsula. There was even a story about the operation of oil rigs off the Louisiana coast being threatened as the result of an inability to obtain supplies of certain oil products needed for their continued functioning.

Now it is simply insane that such vital activities should suffer for a lack of oil—that even the production of oil itself should be threatened. In a free market, this could never happen. Such vital uses of oil would always be able to outbid any less urgent employment for all the oil they required. But under price controls even these most vital employments were prohibited from outbidding any other employment that could pay the controlled price.

Price controls simply paralyze rational action. In effect, they bring together at an auction for the use of oil a trucker needing fuel to deliver food supplies and a housewife needing gasoline to take an extra shopping trip to the supermarket, and they prohibit the trucker from outbidding the housewife. They bring together oilmen needing lubricants for their wells and homeowners seeking oil to heat their garages, and they prohibit the oilmen

from outbidding the homeowners. In a word, price controls make it *illegal to act rationally*.

5. The Economic Harmonies of Cost Calculations in a Free Market

We can now understand even more fully than was possible earlier how in a free market the production of each good is carried on in a way that is maximally conducive to production in the rest of the economic system. For we are now in a position to understand more fully how the concern with costs of production promotes the production of other goods every time it leads to the substitution of lower-priced factors of production in limited supply for higher-priced ones, such as the use of unskilled labor where skilled labor was previously required, or the use of a less expensive quantity of aluminum where a more expensive quantity of copper was previously required, and so on. All we have to do is keep in mind that the less expensive factors in limited supply *are* less expensive because the importance of their marginal products to the consumers is less. To substitute less expensive factors for more expensive ones, therefore, is to make it possible for the consumers to obtain products to which they attach greater marginal importance at the expense of products to which they attach smaller marginal importance. For the more expensive factors are released to uses of greater importance than those from which the less expensive factors are withdrawn.

Thus, the fact that in a free market production is carried on at the lowest possible cost that businessmen can achieve means that the production of each thing is carried on not only with the least possible amount of labor, but with *those specific types of labor and other factors of production in limited supply whose use represents the least possible impairment of the satisfaction of alternative wants*.

We can observe the operation of this principle in every cost calculation that businessmen make. To take some examples, let us assume that a railway company is contemplating the extension of its line across a body of water or that an electric company is contemplating the construction of additional generating capacity. In these cases, and in practically every other case, alternative methods of production are possible. The railway could build a bridge across the water, it could tunnel under the water, build a ferry, or, perhaps, detour around the body of water. In each instance, a variety of further alternatives are possible, such as where to construct the bridge, what materials and design to use, and so on. In the same way, the electric company could build a coal-powered plant, a water-powered plant, an oil or gas-powered plant, or an atomic-powered plant. Again, major variations are pos-

sible in each of these alternatives.

Now each method of production and each variant of any given method requires some different combination of factors of production in limited supply. Each of these factors of production has its own alternative uses in various other employments. For example, the bridge requires workers with the special skills required to build bridges. These workers could be employed in building bridges elsewhere or in building skyscrapers, or, of course, in a variety of lesser jobs. The tunnel requires the special skills of sandhogs. These men may first have to be trained, and then a long period of time will go by during which they are unavailable to produce a different variety of goods than the bridge builders. Again, different methods require different combinations of materials that may themselves be in limited supply or require different combinations of labor skills or limited materials in their own production.

The point here is that the selection of any given method of production has its own unique impact on the rest of the economic system in terms of withdrawing factors of production from possible alternative employments. The fact that businessmen select the lowest-cost methods of production means that they try to produce each good with the least overall impairment of the production of alternative goods. Because to produce at the lowest cost means to use that combination of factors of production in limited supply that has the lowest total marginal significance in alternative employments.

Not only is the production of each good harmoniously integrated with the production of all other goods in a free market, but so too, not surprisingly, is the consumption of each good. As we have seen, insofar as any good is produced by factors of production in limited supply, its price reflects the competitive bidding of the consumers of all the products of those factors. For example, the price of bread in a free market reflects the competitive bidding of the consumers of all wheat products for the use of wheat; the price of gasoline in a free market reflects the competitive bidding of the consumers of all oil products for the use of crude oil; and so on. Going still further, the price of wheat and wheat products relative to the price of oil and oil products reflects the competitive bidding of the consumers of all wheat products relative to the competitive bidding of the consumers of all oil products. Indeed, the prices of all factors of production in limited supply and of their respective products reflect the relative utilities of the respective marginal products to the ultimate consumers. The consumer buyers of any of these products, therefore, when they take account of their prices, are led to pay the same regard to the rest of the economic system as businessmen when they make cost calculations.

More on the Response to the Oil Embargo

The above facts about the harmonious integration of the production and consumption of each good into the rest of the economic system also have application to how a free market would have responded to the Arab oil embargo.

If we had had a free market, the response to the reduction in the supply of oil would have been based on the exercise of the intelligence and judgment of each and every individual businessman and consumer in the economic system.

As the price of oil and oil products rose, each individual businessman and consumer would have decided where and to what extent to cut back on the use of oil by consulting his own individual circumstances. Those businessmen would have cut back who had lower-cost alternatives available. For example, businessmen with the alternative of switching to coal or shipping by rail or barge instead of truck would have done so. And more and more would have done so, more and more rapidly, as the price of oil and oil products rose higher, because the comparative savings in doing so would have become greater. In the same way, some firms might have concentrated their production in fewer days to conserve fuel. Some might have concentrated production more heavily in plants in warmer parts of the country. Some might have reduced or stopped production entirely, because of an inability to sell as many goods at the higher prices necessitated by higher costs of fuel and transportation. The point is that there would have been as many *individual* responses as there were separate business firms and even subunits within business firms. The response in each case would have been based on a consideration of costs and alternatives in the individual case.

Similarly, each individual consumer would have decided where and to what extent to cut back on the basis of the individual circumstances confronting him. What would have decided in each case was the importance of the particular oil product, as determined by the individual consumer's personal needs and desires dependent on that product, and the extent of his wealth. For example, no one to whom time was essential would have been forced to reduce his driving speed. Nor would a wealthy person have been forced to give up driving his Cadillac. By the same token, no one whose only means of getting to work was an automobile would have gone without gasoline. He would have chosen to go without other things first and to spend the money he saved from somewhere else, to buy the necessary gasoline. Anyone in such a position would have been assured of all the gasoline he required, because he would certainly have been willing and able to pay more for gasoline for the purpose of getting to work than most other people would have been willing to

pay for it for any lesser purpose. To obtain gasoline for getting to work, one would merely have had to outbid other people seeking gasoline for pleasure trips, marginal shopping trips, and so on.

More broadly, since more gasoline can always be produced from crude oil made available by producing less of other oil products, an individual needing gasoline to get to work would merely have had to outbid other people requiring the use of *crude oil* for any lesser purpose than one comparable to that of getting to work. For example, he would have been able to obtain gasoline by outbidding even people far richer than himself who previously used oil to heat their swimming pools, or, perhaps, who previously consumed vegetables or flowers grown in hothouses with the aid of large quantities of oil.

The specific ways in which oil would have been economized are far too numerous to name. It is impossible even to learn them all. They would have depended on an enormous number of individual circumstances, in many cases known only to the individuals directly involved, whoever and wherever they might have been.

The essential fact is that oil would have been economized in ways that affected each individual as little as possible. Each individual—businessman and consumer—would have dealt with the problem in the way best suited to his own business or personal context, and at the same time his efforts would have been harmoniously integrated—through the price of oil and oil products—with the like efforts of everyone else. Each would have acted on the basis of the price of oil and oil products, and the circumstances and judgments of each would have determined just how high those prices would have had to go before the quantity of oil and oil products demanded was levelled down to equality with the reduced supply of crude oil available. In other words, *in a free market, the oil crisis would have been met by the conscious planning of each individual, harmoniously integrated with that of every other individual.*

Of course, this is not what occurred—because of price controls. All considerations of individual context were dropped. The intelligence and planning of the individuals were paralyzed, as we have already seen. The government's solution was a sledgehammer approach that disregarded all individual circumstances and context. It arbitrarily curtailed the use of oil and oil products for whole categories of employments. For example, it declared that the airline industry would operate on 80 percent of its previous year's fuel, that farmers would have to make do with so much less propane, and that everyone would have to drive at no more than fifty-five miles per hour and set his thermostat at no more than sixty-eight degrees. This absurd approach simply ig-

nored which industries and which specific firms and individuals could really afford to cut back on oil, and just where. It disregarded such elementary facts as that lower truck speeds would require proportionately more trucks and man-hours to haul the same amount of freight, so that to arbitrarily save a few gallons of

gasoline, whole trucks and untold man hours to operate them would be wasted. It disregarded the fact that thermostat settings of sixty-eight degrees in some places and for some people can be tantamount to freezing and cause pneumonia. But more of such consequences of price controls soon enough.

Appendix to Chapter 6: The Myth of "Planned Obsolescence"

A popular fallacy—advanced in full contradiction of the uniformity-of-profit principle and its implications for economic progress—holds that businessmen engage in the practice of "planned obsolescence," that is, they allegedly plan for their products to wear out more rapidly than is necessary, in order to create an additional, replacement demand for them.⁴² According to Vance Packard, one of the leading popularizers of this fallacy: "Even the best of products, of course, wears out sometime. Therefore a company cannot be legitimately criticized for estimating the death date of its product. It is vulnerable to criticism, however, if it sells a product with a short life expectancy when it knows that for the same cost, or only a little more, it could give the customer a product with a much longer useful life. In such situations one may properly wonder about the company's motives."⁴³

Despite the prevalence of such beliefs, the fact is that in all cases in which a more durable product can be produced at the same cost of production as a less durable one, the profit motive acts as an inducement to produce the more durable product. Indeed, the profit motive acts as an inducement to produce the more durable product even when its cost of production is substantially greater, provided that the extra durability is sufficiently great.

A simple example will demonstrate why this must be so. Assume that there are two light bulbs costing \$1 each to produce. One lasts 10 times as long as the other. The manufacturers are presently producing the less durable bulb and selling it at a price of \$1.25. Assume that they are presently selling 100 million of these bulbs per year and that if they introduced the longer-lasting bulb, they would sell only 10 million of them per year. The question must be asked: Is it less profitable to sell 10 million longer-lasting bulbs than 100 million of the present bulbs?

The supporters of the planned obsolescence doctrine believe that the answer is yes. But the answer is no.

At present, the manufacturers have sales revenues of \$125 million—\$1.25 per bulb times 100 million bulbs. They have a total cost of \$100 million—\$1 per bulb times 100 million bulbs. Their present profit, therefore, is \$25 million. Now assume that they introduce the 10-times-longer-lasting bulb. Such a bulb could certainly be sold for 5 times as much as the present bulb. (If it is, the

customer is far better off, for he pays only *half* as much per unit of service life of a bulb as he did before. In fact, he gains at any price below 10 times as much). A price 5 times as high is \$6.25. This price times 10 million bulbs sold, gives sales revenues of \$62.5 million. The manufacturers' total costs are now \$1 per bulb times 10 million bulbs, or \$10 million. Profits, therefore, go to \$52.5 million—more than doubling from their present level!

Manufacturers can increase their profits by introducing the longer-lasting product even if its unit cost is higher, provided that the higher cost is less than proportionate to the product's longer life. For example, even if the 10-times-longer-lasting bulb cost 9 times as much to produce, or \$9, the manufacturers could still increase their profits substantially. If they offered the bulb at a price of \$12, which would still represent a saving to the consumers, they could increase their profits by \$5 million. They would have sales revenues of \$120 million and total costs of \$90 million, leaving them with a \$30 million profit instead of a \$25 million profit.

As a rule, the only time it would not pay to introduce a longer-lasting good is if it has a higher cost which is more than in proportion to its longer life. For example, it would be absurd to introduce a 10-times-longer-lasting bulb which cost 50 times as much to produce. There are exceptions to this rule, however. In some cases, the convenience of not having to replace a product as often could be so significant as to outweigh a cost more than in proportion to its longer life. Thus, a light bulb lasting 10 times as long and which could be profitable only at a price of 11 times as much, might be successful simply because it would save time in changing bulbs, reduce the risk of falling from ladders, and so on. On the other hand, an automobile which would last twice as long and which had to be sold at twice the price would not make economic sense. Such an automobile would require that people tie up twice the sum of money (and, if they bought on credit, pay twice the interest) and not derive any compensating advantage. A 2-times-longer-lasting automobile would only make sense if it could be sold profitably at a price significantly less than double, perhaps 1.8 or even 1.7 times the price of the present car. (Interest rates would play a major role in determining how large

the saving had to be.)

What the above examples demonstrate is that not only consumers but also manufacturers derive a gain from the introduction of longer-lasting products, provided only that such products are not disproportionately more expensive to produce. The fact that manufacturers might sell a smaller number of units of longer-lasting goods because of the reduced need to replace them, is altogether irrelevant. Any profits which they must forgo as a result of reduced volume can easily be made up in the price of the quantity they continue to sell, together with a major increase in their profits. To understand the principle involved, it is only necessary to realize two things. First, as an upper limit, the price of the longer-lasting product can be raised approximately in proportion to its greater durability. Second, only a relatively small price increase is required to make up for the profits lost on the quantity no longer produced. Any price in between these limits represents both a saving to the consumer and additional profits to the producer.

To make this clear, let us return to our example of the light bulbs. If the present light bulb is sold for \$1.25, a 10-times-longer-lasting one could be sold at a potential upper limit of \$12.50. At any price lower than \$12.50, the consumers have a clearcut gain. While the manufacturer's volume is cut to one-tenth of its initial level, the profit he loses is only 25¢ on each bulb. Since he no longer sells 9 bulbs for every one which he continues to sell, he must be compensated to the extent of \$2.25 in the price of the longer-lasting bulbs. If the longer-lasting bulb costs \$1 to produce, then the manufacturer needs a price of only \$3.50 to make as much profit on one-tenth the quantity of bulbs as he did on the initial quantity. At any price greater than \$3.50, his profits increase. Any price greater than \$3.50 and less than \$12.50 thus represents a gain to both the consumers and the producers. (If the longer-lasting bulb costs \$9 to produce, the manufacturer must have a price greater than \$11.50 to come out ahead.)

Consider wider illustrations. Profits are only a small percentage of sales—5 percent, 10 percent, on rare occasion 20 percent. Assume profit is 20 percent of sales—for example, a manufacturer has costs of 80, profits of 20, and sales of 100. If his physical volume were to be cut in half, while his unit cost and selling price remained the same, he would have costs of 40, profits of 10, and sales of 50. His profits could be restored to 20, however, if he could raise his price by 20 percent, thus raising his sales revenues from 50 to 60. If the halving of his sales volume is the result of a doubling of his product's life, there can be no doubt about his ability to raise his price by 20 percent—the upper limit by which he could raise it is 100 percent. Observe. In this case, the manufacturer only

needs a price rise in excess of 20 percent to come out ahead, while the conditions of the case permit a price rise as high as 100 percent. Suppose the manufacturer's sales volume is reduced to a third of its initial level, as a result of his introducing a product which lasts 3 times as long. The potential upper limit of his price increase is now 200 percent. But all he needs to come out ahead is a price increase of 40 percent—40 percent more on a third of his initial volume will give him the same profits he made on the other two-thirds, if his initial profit margin was 20 percent. Similarly, if his volume is cut to a fourth of its initial level, as a result of quadrupling his product's life, then while the upper limit of the price rise goes to 300 percent, the manufacturer only needs a price rise in excess of 60 percent to come out ahead.

If we change the assumed profit margin to 10 percent, then a mere 10 percent rise in price restores profits when volume is cut to a half of its initial level, a 20 percent rise restores profits when volume is cut to a third of its initial level, and so on. With a 5 percent profit margin, a 5 percent rise in prices restores profits when volume is cut to a half, and a 10 percent rise in prices restores profits when volume is cut to a third of its initial level, and so on. The upper limits by which prices might be raised in these cases, however, continue to be 100 percent, 200 percent, and ever more, to the degree that volume is cut as a result of the introduction of longer-lasting products.

The principle which emerges is the following. The consumers are willing to pay an increase in price equal to as much as one less than the multiple of durability times the product's initial price. (For example, if the product is made 10 times more durable, the consumers are willing to pay an increase in price equal to 9 times the product's initial price.) To come out even, however, the manufacturers require a price increase equal merely to one less than the multiple of durability times the product's initial *profit margin*—for example, 9 times 20 percent, 9 times 10 percent, or 9 times 5 percent. Between a multiple of the initial price and an equal multiple of the initial profit margin is an enormous field for mutual gain to both consumer and producer. This field is so great that any necessary writeoffs of existing plant and equipment could easily be compensated for along with profits forgone on lost volume.⁴⁴

Perhaps the best and simplest way to regard longer-lasting products in comparison with less-durable products is in terms of the comparative costs of producing equivalents. If one better light bulb lasts 10 times as long as a present light bulb, it is the equivalent of 10 of the present light bulbs. If the cost of production of both types of bulb is \$1, then what we have is a \$1 cost of production versus a \$10 cost of production of the same equivalent. If the cost of production of the better bulb is \$9, then we

have a case of \$9 versus \$10 as costs of production of the same equivalent. The issue of whether or not manufacturers will introduce longer-lasting products can thus be seen to reduce to the question of *whether or not they prefer lower-cost methods of production to higher-cost methods of production*. They will introduce longer-lasting products whenever the longer-lasting products represent a reduction in the cost of producing equivalents. And they will do so with a rapidity and enthusiasm in direct proportion to the cost reductions to be achieved. To ask if *GE* would introduce a 10-times-longer-lasting light bulb, or *GM* a 2-times-longer-lasting car, having the same unit cost of production as the present light bulb or car, is to ask the equivalent of: Would *GE* introduce a light bulb costing one-tenth as much to produce? Would *GM* introduce a car costing half as much to produce? The answer to both questions is obviously yes.

Thus far, I have deliberately understated the case. I have assumed that the reduction in the quantity of a good demanded would be in full proportion to its greater durability. In fact, this would usually not be so. If a 10-times-longer-lasting light bulb or a 2-times-longer-lasting automobile can be sold at less than 10 or 2 times the price, the quantity demanded will not fall to a tenth or a half, but to some amount greater than a tenth or a half. (Indeed, in some cases, the quantity of the good demanded might even increase, if the demand for it is sufficiently elastic.) The reason, of course, is that in terms of a unit of service life the good is made less expensive and thus tends to be used in larger quantity. This tendency of the quantity demanded to fall less than in proportion to the product's greater life would be powerfully reinforced in every case in which the producer of the longer-lasting product was faced with competitors producing the shorter-lived product. In all cases of this kind, the firm introducing the more durable product would have the entire existing market of its competitors as a potential field for its own expansion. It thus might very well succeed in increasing its physical volume by a substantial multiple.

The fact is that business does not produce less-durable goods in preference to more-durable goods, but the contrary. Nor does it foist undesired fashion changes on the public, or dribble out over time improvements which it has the ability to introduce all at once. These beliefs rest on the fallacy that profitability depends exclusively on

the physical volume of goods sold. In fact, in all these cases, any profits lost as a result of diminished volume, could more than be made up by a relatively modest rise in price on the remaining volume. Consumers would benefit at the same time, because they would save the expense of buying unnecessary units.⁴⁵

Despite the fact that the profit motive leads businessmen to try to produce the highest-quality, longest-lasting products per dollar of cost, it can, of course, be the case that over time the quality of products deteriorates and their life shortens. This is because the beneficial effect of the profit motive can be outweighed by the contrary effect of government interference. For example, prounion legislation can deprive firms of the ability to fire careless workers. Taxation can deprive them of the funds to buy the quantity and quality of the labor, materials, and machinery they would otherwise employ in producing a given quantity of goods. Above all, price and wage controls can lead to a deterioration in the quality and life of products by creating shortages of means of production and by eliminating all the normal, competitive incentives to high-quality production.⁴⁶ The essential point is not that deterioration in the quality and life of products cannot exist, but that the profit motive always acts to improve the quality and lengthen the life of products insofar as it is allowed to operate.

It is conceivable that the objection might be raised to the preceding analysis that it is mistaken in assuming that manufacturers of more-durable products are in a position substantially to increase the prices of such products and thus make up for any reduction in physical volume they might suffer. The objection might be made that freedom of competition would quickly put prices at the same level as they were to begin with. The answer to this objection is that under capitalism whoever introduces a significant improvement in production normally enjoys patent protection, which would secure his ability to obtain the higher price for a sufficient period of time to make the improvement worthwhile.

The doctrine of planned obsolescence is merely one more groundless assault on the profit motive and the pursuit of self-interest. If it does not represent "planned error"—that is, outright malice—it represents such a degree of thoughtlessness as to constitute reckless disregard of facts and logic.

Notes

1. The rate of profit on capital invested should not be confused with the concept of profit margin. A profit margin is profit taken as a percentage of sales revenues, not capital invested. Because of technical factors centering on the periods of time which must elapse between outlays of capital and receipts of sales revenue, different industries tend to earn permanently unequal profit margins, even though they tend to earn equal rates of profit on capital invested. Thus, for example, a retail grocery business, which has a substantial portion of its capital invested in merchandise of the kind that is sold within days of purchase, or even on the very same day, may have annual sales revenues equal to five times its capital. A steel mill, on the other hand, may have annual sales revenues that are merely equal to its capital. An electric utility may have annual sales revenues that are equal to only half of its capital. Because of these very different rates of capital turnover—i.e., ratio of sales to capital—namely 5:1, 1:1, and $\frac{1}{2}$:1, very different profit margins must exist if equal rates of profit on capital invested are to exist. Thus, the profit margin in the retail grocery business would have to be just 2 percent; that of the steel mill, 10 percent; and that of the electric utility, 20 percent, in order for all of them to earn a rate of profit on capital invested of 10 percent.

4. See above, p. 118, n. 80, for a reference to the fact that the validity of this principle has found important recognition within the U.S. government.

5. At that time, \$10,000 represented approximately 500 ounces of gold. To estimate the equivalent in terms of today's money, one should multiply 500 oz. of gold by the currently prevailing price of gold.

6. For elaboration and related discussion of these points, see below, pp. 206–214.

7. See below, pp. 925–927.

8. Cf. Henry Hazlitt, *Economics in One Lesson*, new ed. (New Rochelle, N. Y.: Arlington House, 1979), pp. 114–115.

9. I must point out that it is an error to assume that the repeal of rent controls would create any kind of insuperable problems of short-run hardship. Indeed, I will demonstrate later on that even before sufficient time went by to make possible the construction of any additional new housing, the overall effect of the repeal of rent control would be to improve the conditions of more people than it worsened and to impose no greater hardship on those who had to give up their rent-controlled apartments than was already being experienced, and had been experienced for many years, by just as many other people precisely as the result of rent controls. On this point, see below, pp. 252–254.

10. See above, pp. 63–66 and 90–91.

11. See below, pp. 201–202.

12. See above, n. 1 of this chapter, for an explanation of the relationship between the rate of profit on the one side, and the rate of capital turnover and the profit margin on the other.

13. Of course, the absence of price changes is possible only if the changes in demand are within certain limits. If increases in demand are so great as either completely to outstrip the ability of the industry to meet them from existing capacity, or to require the use of older, substantially less efficient, higher-cost capacity, product prices must rise. It is only a question of by how much. Similarly, if the fall in demand is so substantial that one or more firms finds that the quantity of their products demanded is insufficient to enable them to operate even their most efficient lowest-cost capacity at an adequate rate, while other firms are still using substantially less efficient, higher-cost capacity, then it will be to the interest of such firms to cut prices below the operating costs of others' less efficient capacity. This will enable their efficient capacity to displace the others' less efficient capacity. The price cut in these circumstances will be profitable to the firms which make it, because continued operation of high-cost capacity by others is thereby made unprofitable, with the result that the price-cutting firms secure substantial additional business that is profitable to them. See below, p. 436, for the application of this point to a critique of the doctrine of pure and perfect competition and the Marshallian doctrine of the representative firm.

14. Cf. Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), p. 245.

15. *Ibid.*

16. It is standard practice in contemporary economics to consider the portion of the profits of small businessmen which is comparable to the compensation they could earn as wage earners as though it actually were wages. For a critique of this practice, see below, pp. 459–462.

17. This has already been indicated in connection with the uniformity-of-profit principle. See above, p. 185.

18. For an analysis of the actual process of adjustment in wages and prices that would follow the adoption of a policy of unilateral free trade or unilateral tariff reduction, and of the consequences if other countries simply refused to allow the goods of the country in question into their territory while it pursued a policy of free trade, see below, pp. 535–536.

19. The fact that speculators must lose in the absence of an independently caused rise in the demand for and price of the commodity they speculate in is confirmed by the following supply-and-demand diagram. The diagram shows that initially, in the absence of speculators, the price of a commodity is p_0 , resulting from the demand DD and the supply SS . The general public buys the entire supply, equal to quantity OA , at the price

p_0 . Now speculators appear on the scene, and when their demand is added to that of the general public, the total demand for the commodity rises from DD to $D'D'$. The result is that the price rises from p_0 to p_1 . At the higher price, the general public reduces its purchases from the full supply, OA , to the part of the supply represented by OB . The speculators buy up the part of the supply represented by AB . If the speculators bought the quantity AB all at once, they would have to pay a price of p_1 for it. In the absence of an increase in demand on the part of the general public, the speculators would then have to sell back their supply at a price of p_0 , if they sold it back all at once. The fact that they would probably buy the quantity AB in increments and sell it back in increments changes nothing fundamental, because the purchase and sale of each increment is described by exactly the same analysis. In addition, there is the further problem of a likely movement of the quantity supplied to somewhere to the right of the line SS , in response to the rise in price. For further discussion of why speculators must lose in the absence of an independent cause of higher future prices, see below, pp. 224–225.

20. Indeed, in 1991, the attorneys general of several states renewed the accusation in new lawsuits that they brought against various oil companies.

21. See George Reisman, *The Government Against the Economy* (Ottawa, Ill.: Jameson Books, 1979), pp. 29–30, Table 1.

22. For an important exception to the principle that sellers are led to sell too rapidly, see below, pp. 225–226.

23. The substance of the following discussion concerning the opposition between capitalism and arbitrary discrimination has been excerpted, with minor modification, from my pamphlet *Capitalism: The Cure for Racism* (Laguna Hills, Calif.: The Jefferson School of Philosophy, Economics, and Psychology, 1992). The pamphlet originally appeared as a six-part article in *The Intellectual Activist* in 1982.

24. See below, pp. 367–371, 584–585, and 663–664. See also *Capitalism: The Cure for Racism*, pp. 6–8.

25. On these points, see George Reisman, *Capitalism: The Cure for Racism*, pp. 12–14. What is described here is government-inspired bureaucratic management taking the place of profit management. On this subject, see Ludwig von Mises, *Bureaucracy* (1944; reprint ed., New Rochelle, N. Y.: Arlington House, 1969), pp. 64–73. See also below, pp. 304–305.

26. On this subject, see below, pp. 382–385.

27. For an account of the precise nature of all the government intervention that has blocked the benevolent operation of capitalism on behalf of blacks in their capacity both as wage earners and as consumers, not only in the South but also in the North, see George Reisman, *Capitalism: The Cure for Racism*, pp. 10–28. See also below, pp. 375–376 and 382–385.

28. This accords with the views of the great classical economist David Ricardo. See David Ricardo, *Principles of Political Economy and Taxation*, 3d ed. (London, 1821), chap. 30 especially; reprinted as vol. 1 of *The Works and Correspondence of David Ricardo*, ed. Piero Sraffa (Cambridge: Cambridge University Press, 1962).

29. See above, p. 168.

30. Wage rates are explainable in terms of supply and demand analysis even in cases in which they are imposed arbitrarily by labor unions or governments. For in such cases, an essential

part of the process is an artificial restriction of the supply in the face of a given demand.

31. As previously indicated, this analysis of the relation between cost of production and supply and demand is the work of the great economist Eugen von Böhm-Bawerk, one of the founders of the Austrian school of economics. Very similar ideas are also propounded by John Stuart Mill, the last major representative of the British classical school. Cf. Eugen von Böhm-Bawerk, *Capital and Interest*, 3 vols. (South Holland, Ill.: Libertarian Press, 1959), 2:168–176 especially, but also 2:248–256 and 3:97–115; John Stuart Mill, *Principles of Political Economy*, Ashley ed. (1909; reprint ed., Fairfield, N. J.: Augustus M. Kelley, 1976), pp. 442–468. As previously noted more than once, a lengthy quotation from Böhm-Bawerk, expressing the substance of his views on the relationship between cost of production and prices appears below, on pp. 414–416.

32. Submarginal land, such as most deserts and mountains, is limited from a mathematical point of view, but stands beyond the limit of the supply of economically useable land. Its limitation in this latter sense provides it with no economic value, for it has zero marginal utility.

33. See above, pp. 152–169 passim, especially p. 158, and below, pp. 219–220. See also below, pp. 503–505.

34. While the economic system is in process of adjusting to a change in the quantity of money, the demand for the various goods and services is affected unevenly. Cf. von Mises, *Human Action*, pp. 412–414; idem, *The Theory of Money and Credit*, new ed. (1953; reprint ed., Irvington-on-Hudson, N. Y.: The Foundation for Economic Education, 1971), pp. 137–141. Von Mises argues that there are also permanent effects on the relative demands for the various goods and services, and thus on their relative prices.

35. See above, p. 169.

36. Of course, government intervention can deprive people of the ability to rent space they can afford to rent, by declaring such space to be substandard and its rental illegal. Such government intervention causes homelessness. See below, pp. 384–385.

37. See below, pp. 503–526 and 895–963 passim.

38. For elaboration of this vital fact and of its significance, see below, pp. 613–618 and 618–664 passim.

39. Cf. above, pp. 49–50.

40. This insight is one of the great contributions of Böhm-Bawerk. See above, p. 52 and the present chap., n. 31.

41. The results that will be derived from the present case could also be derived from the case of opposite changes in the demand for products of iron and products of cotton that was used earlier in connection with establishing additional causes of the tendency toward a uniform rate of profit. See above, p. 184.

42. This appendix, with minor revision, is drawn from the author's article of the same title which originally appeared in *Il Politico* 38, no. 3 (September 1973). It appears by permission of the publisher.

43. Vance Packard, *The Waste Makers*, Giant Cardinal ed. (New York: Pocket Books, Inc., 1963), p. 49.

44. For a demonstration of this fact, see my above-referenced article from which the present discussion is drawn, pp. 485–486.

45. For elaboration on these points, see *ibid.*

46. On these destructive effects of price controls see below, pp. 219–264 passim.

CHAPTER 7

THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM III: PRICE CONTROLS AND ECONOMIC CHAOS

PART A

PRICE CONTROLS AND SHORTAGES

1. Price Controls and Inflation

Knowledge of the dependence of the division of labor on capitalism deepens profoundly with an understanding of the destructive consequences of price controls, which are the subject matter of the present chapter.

Price Controls No Remedy for Inflation

Price controls are advocated as a method of controlling inflation. People assume that inflation means rising prices and that it exists only when and to the extent that businessmen raise their prices. It appears to follow, on this view, that inflation would not exist if price increases were simply prohibited by price controls.

Actually, as we shall see later in this book, in Chapters 12 and 19, this view of inflation is utterly naïve. Rising prices are merely a leading *symptom* of inflation, not the phenomenon itself. Inflation can exist, and, indeed, accelerate, even though this particular symptom is prevented from appearing. Inflation itself is not rising prices, but an unduly large increase in the quantity of money,

caused, almost invariably, by the government. In fact, a good definition of inflation is, simply: an increase in the quantity of money caused by the government. A virtually equivalent definition is: an increase in the quantity of money in excess of the rate at which a gold or silver money would increase. These two definitions are virtually equivalent, because without government interference in money over the course of our history, the supply of money today would consist mainly or even entirely of precious metals and fully backed claims to precious metals. The increase in the supply of such a money would almost always be quite small and at all times would be severely limited by the high costs of mining additional quantities of the precious metals. Rising prices as a chronic social problem are a consequence of the government's overthrow of the use of gold and silver as money and putting in their place irredeemable paper currencies whose quantity can be increased without limit and virtually without cost.

Because it is necessary to approach the subject of price controls with clear ideas about why prices chronically rise in the world around us, it is necessary to anticipate here some of the discussion of later chapters and to show in no uncertain terms that the quantity theory of money—viz., the increase in the quantity of money—is the only valid explanation of the phenomenon.¹

The truth of the quantity theory of money follows

from the best known principle in the theory of prices, which is that prices are determined by demand and supply and vary directly with demand and inversely with supply. By *demand* in this context is to be understood the willingness combined with the ability to spend money, and by *supply*, the existence of goods combined with the willingness to sell them. Demand manifests itself in the spending of money; supply, in the quantity of goods sold.²

When people complain of “inflation,” what they have in mind is not an isolated rise in some prices here and there, offset by a fall in prices elsewhere, but a rise in prices in general, that is, a rise in the general consumer price level. The general consumer price level is the weighted average of all consumer prices.

It follows from the law of supply and demand that the general consumer price level can rise only if the aggregate demand (the total spending) for consumers’ goods rises, or the aggregate supply (the total quantity sold) of consumers’ goods falls. Indeed, the general consumer price level can be conceived of—as it was by the classical economists—as an arithmetical quotient, with demand (spending) as the numerator and supply (quantity of goods sold) as the denominator, for the average of the actual prices at which things are sold *is*, literally, nothing more than the total spending to buy them divided by the total quantity of them sold. In effect, in any given year, some definite mass—however measured—of houses, cars, soap, matches, and everything else in between, exchanges against some definite overall expenditure of money to buy them, and the result, the arithmetical quotient, *is* the general consumer price level.³

Rising prices in the United States are obviously not the result of falling supply, since supply has been growing in practically every year. The same is true of the countries of Western Europe, Japan, and even many of the Latin American countries. There can be no question, therefore, but that the rise in prices in these countries can be the result only of an increase in aggregate demand. Moreover, in the few cases in which supply appears to have fallen, such as Chile and Uruguay in the late 1960s and early 1970s, the rise in prices was enormously out of proportion to any possible decrease in supply in those countries. In those countries above all, demand grew.⁴

An increase in aggregate demand is the result of an increase in the quantity of money in the economic system. When new and additional money enters the economic system, whether it is newly mined gold in a country using gold as money, or newly created paper currency or checkbook money, as in the present-day United States, that money will be spent, and those who receive it in the sale of their goods and services will spend it. The additional money will be spent and re-

spent in every year of its existence, thereby raising aggregate demand and spending in the economic system to a correspondingly higher level. Indeed, the more rapidly new and additional money enters the economic system, the more rapidly the previously existing quantity of money tends to be spent, because people progressively lose the desire to hold balances of such money.⁵ (For example, who wants to hold Argentine pesos? Who wants to hold U.S. dollars as much today as a generation ago?) Aggregate demand and spending thus begin to rise more than in proportion to the increase in the quantity of money. The rise in aggregate demand is what bids up the prices of all goods and services in limited supply, and is what enables price increases initiated by sellers, whether businessmen or labor unions, to take place as a repeated phenomenon. In the absence of the rise in aggregate demand, price increases initiated by sellers would reduce the amount of goods and services that could be sold. This loss of sales volume, and the mounting unemployment that goes with it, would soon put an end to such price increases.⁶

Once the truth of the quantity theory of money is recognized, the government’s responsibility for rising prices follows immediately. Under the conditions of the last seventy-five years or more, the government has had virtually total control over the quantity of money. It has deliberately brought about its rapid increase. Since the inauguration of the New Deal in 1933, the quantity of money in the United States has been increased by more than 58-fold, from little more than \$19 billion to well over \$1,100 billion at the end of 1993. Since 1955, the rate of increase has shown a pronounced tendency to accelerate, despite the absence of any major war. Today, rates of increase are considered “normal” and even “modest” that a generation ago would have been considered huge.⁷

Inflation Plus Price Controls

The imposition of price controls to deal with inflation does not stop inflation. Rather it *combines* with inflation to produce a different and worse set of consequences than would inflation alone. It is as illogical—and as self-destructive—as would be an attempt to deal with expanding pressure in a boiler by means of manipulating the needle in the boiler’s pressure gauge. The last two chapters have shown, in effect, that prices are equivalent to an instrument panel on the basis of which everyone plans his economic activities and which enables the plans of each individual to be harmoniously adjusted to the plans of all other individuals participating in the economic system. When price controls are imposed, the gauges on this instrument panel are frozen. Not only do the gauges no longer record the fact of inflation, which still continues

and probably accelerates because the government need no longer fear rising prices, but the gauges also no longer reflect any other aspects of the state of supply and demand, which people must be able to take into account if their actions are to be coordinated with one another. Thus, economic activity under the division of labor becomes discoordinated and chaos ensues. It follows, and every page of this chapter will confirm it, that a government which imposes price controls is in process of destroying the economic system of its own country.

2. Shortages

We have seen that the price system of capitalism—the free market—constitutes a rational, ordered system of social cooperation; indeed, that it is a truly awe-inspiring complex of relationships in which the rational self-interest of individuals unites all industries, all markets, all occupations, all production, and all consumption into a harmonious, progressing system serving the well-being of all who participate in it.

All of this is what price controls destroy.

The one consequence of price controls that is the most central and the most fundamental and important from the point of view of explaining all of the others, and which most directly threatens the ability to produce under the division of labor, is the fact that *price controls cause shortages*.

A shortage is an excess of the quantity of a good buyers are seeking to buy over the quantity sellers are willing and able to sell. In a shortage, there are people willing and able to pay the controlled price of a good, but they cannot obtain it. The good is simply not available to them. Recalling the gasoline shortage of the winter of 1974 should make the concept real to everyone who experienced it. The drivers of the long lines of cars all had the money that was being asked for gasoline and were willing, indeed, eager, to spend it for gasoline. Their problem was that they simply could not obtain the gasoline. They were trying to buy more gasoline than was available.

The concept of a shortage is not the same thing as the concept of a scarcity. An item can be extremely scarce, like diamonds, Rembrandt paintings, and so on, and yet no shortage exist. In a free market, as we saw in the last chapter, the effect of such a scarcity is a high price. At the high price the quantity of the good demanded is levelled down to equality with the supply available, and no shortage exists. Anyone willing and able to pay the free-market price can buy whatever part of the supply he wishes; the height of the market price guarantees it, because it eliminates his competitors. It follows that however scarce a good may be, the only thing that can

explain a shortage of it is a price control, not a scarcity. It is a price control that prevents the price of a scarce good from being raised by the self-interest of the buyers and sellers to its free-market level and thus reducing the quantity of the good demanded to equality with the supply of the good available.

Of course, if a price control on something exists, and a scarcity of it develops or grows worse, the effect will be a shortage, or a worsening of the shortage. Scarcities can cause shortages, or worsen them, *but only in the context of price controls*. If no price control existed, the development or worsening of a scarcity would not contribute to any shortage; it would simply cause the price to be higher.

It should be realized that a shortage can exist despite a great physical *abundance* of a good. For example, we could easily develop a severe shortage of wheat in the United States even with our normally very abundant supplies, or even much larger supplies. This is because the quantity of wheat demanded depends on its price. If the government were to roll back the price of wheat sufficiently, it would create a major increase in the quantity demanded—not only a larger quantity demanded for export, but a larger quantity demanded for raising cattle and broilers, making whiskey, and perhaps for many other employments for which one does not presently think of using wheat, because of its price. In other words, no matter how much wheat we produced, we could have a shortage of it, because at an artificially low price we could create a demand for an even larger quantity.

It should be held in mind, therefore, that shortages are not a matter of scarcity or abundance. Scarcity need not cause them; abundance is no safeguard against them. Shortages are strictly the result of price controls. Price controls are the only thing that allows scarcities to cause shortages; and they create shortages even when there is no scarcity, but abundance.

Indeed, the true relationship between scarcities and shortages is the *reverse* of what is usually believed. While scarcities per se do not cause shortages, *shortages cause scarcities*. That is, no matter how abundant are the supplies with which we begin, we have only to impose price controls, create shortages, and we will soon bring about growing scarcities. As an example of this, consider the fact pointed out in the last chapter that in the oil crisis oilmen needing oil products to keep their wells running were prohibited from outbidding homeowners needing oil to heat their garages. It is obvious what such a situation is capable of doing to the subsequent supply of oil.

The fact that it is shortages that cause scarcities will be a recurring theme of this chapter.

In a free market shortages are a virtual impossibility.

The closest thing that exists to them is that sometimes people may have to wait in line for the next showing of a popular movie. The typical case in a free market is that a seller is in a position to supply more than his present number of customers. There are very few stores or factories in a free market that are not able and eager to do more business. Even goods and services in limited supply are priced in such a way that the sellers are usually able and willing to do more business. For example, the wine shops have some reserve inventory of the rare wines. Landlords have a certain number of vacancies. There is even some limited degree of unemployment in most occupations. This is because, in a free market, the prices of goods and services in limited supply are set somewhat above the point that would enable the sellers to sell out entirely and the workers to be 100 percent employed. The reason prices are set in this way is because the sellers, including the workers, believe that by waiting before they sell, they can find better terms. They are holding out, waiting for the right customers or the right job.

3. Price Controls and the Reduction of Supply

The preceding discussion showed how price controls create shortages by artificially expanding the quantity of a good demanded. To the degree that the controlled price is below the potential free-market price, buyers judge that they can afford more of the good with the same monetary wealth and income. They judge that they can carry its consumption to a point of lower marginal utility. In this way, the quantity of the good demanded comes to exceed the supply available, whether that supply is scarce or abundant.

Price controls also reduce supply, which intensifies the shortages they create.

a. The Supply of Goods Produced

In the case of anything that must be produced, the quantity supplied falls if a price control makes its production unprofitable or simply of less than average profitability.

It is not necessary that a price control make production unprofitable or insufficiently profitable to *all* producers in a field. Production will tend to fall as soon as it becomes unprofitable or insufficiently profitable to the highest-cost or *marginal* producers in the field. These producers begin to go out of business or at least to operate on a smaller scale.

For example, the price controls on oil held down the supply of oil. They did not totally destroy the supply of oil, but they did discourage the development of high-cost domestic sources of supply. They also made the more intensive exploitation of existing oil fields unprofitable,

which fields can be made to yield from one-third to two-thirds more oil over their lives by the adoption of such methods as thermal or chemical flooding, sometimes known as “tertiary recovery.” At the same time, in restricting the profits from the lower-cost oil deposits, price controls held down both the incentives to discover and develop new such deposits and the capital necessary to the oil companies for expanded oil operations of any type. Thus, it should not be surprising that following the repeal of price controls on oil in 1981, a major surge in domestic drilling and production occurred—despite the fact that the government imposed a confiscatory “wind-fall-profits tax” that deprived the oil companies of a major part of the benefit of the repeal of the price controls. For now domestic oil production became more profitable.

Rent controls on housing that has already been constructed provide a similar example of the destruction of supply. As inflation drives up the operating costs of housing—namely, such costs as fuel, maintenance, and minor repairs—more and more landlords of rent-controlled buildings are forced to abandon their buildings and leave them to crumble. The reason is that once the operating costs come to exceed the frozen rents, continued ownership and operation of a building become a source merely of fresh losses, over and above the loss of the capital previously invested in the building itself.

This destruction of the housing supply starts with the housing of the poor and then spreads up the social ladder. It starts with the housing of the poor because the operating costs of such housing are initially so low that they leave relatively little room for economies. For example, there are no doormen to eliminate and therefore no doormen’s salaries to save. Also, the profit margins on such housing (that is, profits as a percentage of rental revenues) are the lowest to begin with, because the land and the buildings are the least valuable and therefore the amount of profit earned is correspondingly low. As a result, the housing of the poor is abandoned first, because it provides the least buffer between rising operating costs and frozen rents.

b. The Supply of Goods in a Local Market

A price control reduces supply whenever it is imposed in a local market and makes that market uncompetitive with other markets. In such a case, the local market is prevented from drawing in supplies from other areas, as was the Northeast and the United States as a whole during the Arab oil embargo.

The Natural Gas Crisis of 1977

In exactly the same way, in the winter of 1977, price controls on natural gas prevented areas of the United

States that were suffering freezing weather from bidding for additional supplies from the producing regions in the South and Southwest. Natural gas shipped across state lines was controlled by the Federal Power Commission at a maximum of \$1.42 per thousand cubic feet. Natural gas sold within the states where it was produced, and thus outside the jurisdiction of the FPC and free of price controls, was selling at \$2.00 per thousand cubic feet, with lower costs of transportation besides. It was therefore much more profitable to sell natural gas in the states where it was produced, such as Texas and Louisiana, than in such states as New Jersey or Pennsylvania.

Indeed, in the absence of government controls over the physical distribution of supplies, price controls would have resulted in still less gas being shipped outside the producing states and more being sold inside, in accordance with the difference in price and profitability. This process would have gone on until enough additional gas was retained within the markets of the producing states to make its price in those markets actually fall below the controlled interstate price by an amount equal to the costs of transportation; only at that point would it have paid producers to ship their gas out of state. The shortage in the rest of the country, of course, would have been correspondingly more severe. As I say, government controls over the physical distribution of natural gas prevented this outcome; the government simply forced the gas producers to sell a major part of their output in the interstate market. But the government's allocation formulas did not take into account the extremely cold winter of 1977, and its allocations proved inadequate to keep people from the threat of freezing. Price controls then prevented the people of the affected regions from obtaining the additional supplies they urgently needed.⁸

The Agricultural Export Crisis of 1972–73

A price control not only prevents a local market from drawing in supplies from elsewhere, but it can also cause a local market that normally exports, to export excessively. In this case, as supplies are drawn out, the price control prevents the people in the local market from bidding up the price and checking the outflow.

This phenomenon occurred in the United States in 1972 and 1973. Our price controls on wheat, soybeans, and other products made possible an unchecked exportation that jeopardized domestic consumption and led to an explosion of prices each time the controls were taken off, in President Nixon's succession of on-again, off-again "phases" of price controls.

In this instance, the fall in the value of the dollar in terms of foreign currencies played a critical role. When President Nixon imposed price controls in August of 1971, he also took steps to devalue the dollar by 10

percent. Over the following two years, the dollar continued to fall in terms of foreign currencies and in 1973 was formally devalued a second time. The fall in the dollar's foreign exchange value meant a lower price of dollars in terms of marks, francs, and other currencies. Since the prices of our goods were frozen, a lower price of dollars meant that all of our goods suddenly became cheaper to foreigners. As a result, they began buying in much larger quantities—especially our agricultural commodities. As they began buying, domestic buyers were prevented by price controls from outbidding them for the dwindling supplies. As a result, vast accumulated agricultural surpluses were swept out of the country, and domestic food supplies were threatened, which is why prices skyrocketed each time the controls were taken off.

Price Controls as a Cause of War

The fact that price controls jeopardize supplies in markets that export leads to embargoes against further exports, as occurred in this country in the summer of 1973, when we imposed an embargo on the export of various agricultural commodities. In addition, price controls in markets that must import make such markets helpless in the face of embargoes imposed by others, as we were made helpless in the face of the Arab oil embargo. It follows that to the degree that countries impose price controls, they must fear and hate each other. Each such country must fear the loss of vital supplies to others, as the result of excessive exportation, and the deprivation of vital supplies from others, as the result of their embargoes and its helplessness to cope with them. Each such country makes itself hated by its own embargoes and hates the countries that impose embargoes against it. Our embargo on agricultural products in 1973 did not endear us to the Japanese. And there was actual talk of military intervention against the Arabs. Simply put, price controls breed war. A free market is a necessary condition of peace.

c. The Supply of Goods Held in Storage

A price control reduces supply whenever it is imposed on a commodity of the kind that must be stored for future use. The effect of a price control in such a case is to encourage a too rapid rate of consumption of the commodity and thus to reduce supplies available for the future. As we have seen, buyers are led to buy too rapidly by the artificially low price, and sellers are led to sell too rapidly, since the fixity of the controlled price does not enable them to cover storage costs and earn the going rate of profit in holding supplies for future sale.

If the buying public and the professional speculators were unaware of the impending exhaustion of supplies, the effect of sellers placing their supplies on the market

right away would be to depress the current market price below the controlled price. This process would go on until the current market price fell far enough below the controlled price, so that once again it would have sufficient room to rise in the months ahead to be able to cover storage and interest costs. The resulting structure of prices would guarantee the premature exhaustion of supplies.

An elaboration on the example of the deficient wheat harvest will make these points clear.⁹ Assume that in a year of normal wheat supplies, the price of wheat begins at \$1.00 per bushel in the harvest month, when supplies are most abundant, and then rises a few cents per month, to cover the costs of storage and interest, and reaches a peak of \$1.20 in the month immediately preceding the next harvest. Now assume that when the harvest is one month's consumption below normal, the price of wheat should begin at \$1.30 in the harvest month and gradually ascend to something over \$1.50 in the month preceding the following harvest, in order to reduce the quantity of wheat demanded to equality with the smaller total supply available. Assume further that a price control limits the price of the deficient wheat crop to no more than \$1.20 in any month. In this case, when the deficient crop comes in, its value cannot remain even at \$1.20 for very long, because it has no prospect of ever getting above \$1.20; as a result, it will be sold more heavily. It will tend to be sold until the price in the harvest month is driven down to \$1.00, and from there the price will gradually ascend in the succeeding months toward \$1.20. This structure of prices will encourage the same rate of consumption as prevailed in years of normal supplies, and will threaten famine conditions at the end of the crop year.

Hoarding and Speculation Not Responsible for Shortages

Under conditions such as those described above, the buying public sooner or later becomes aware of the fact that supplies will run out. At that point, demand skyrockets, as the buyers scramble for supplies. As soon as this occurs, and it may be very early, the larger supplies that sellers are encouraged to place on the market under price controls are not sufficient to depress the market price below the controlled price, because they are snapped up by the speculative buying of the public, which is aware of the shortage to come. (In our example of wheat, the whole supply would tend to be carried off at the controlled price of \$1.20 per bushel as soon as the public becomes aware of the inevitable shortage of wheat to come.) The consequence of the speculative buying of the public is that the item disappears from the market right away; it is hoarded.

The hoarding of the buying public is not responsible

for the existence of shortages. The public hoards *in anticipation* of shortages caused by the price controls. The public's speculative demand cannot even be blamed for hastening the appearance of a shortage. That too must be blamed on price controls, because in the absence of the controls the additional demand of the public would simply raise prices; at the higher prices, the rise in the quantity of goods demanded would be cut back; prices would rise to whatever extent necessary to level down the quantity demanded to equality with the supply available.

Speculation on the part of the suppliers of goods is likewise blameless for the existence of shortages. Contrary to popular belief, price controls do not give suppliers a motive to withhold supplies, but, as we have seen, an incentive to unload them too rapidly.

There is, of course, an important exception to the principle that price controls give sellers an incentive to sell their supplies too rapidly. This is the case in which the sellers are able to look forward to the repeal of the controls. In this case, a price control makes it relatively unprofitable to sell in the present, at the artificially low, controlled price, and more profitable to sell in the future, at the higher, free-market price. In this case, sellers do have a motive to withhold supplies for future sale.

Even in this case, however, it is still the price control that is responsible for the existence of any shortage that develops or intensifies. In this case, the price control discriminates against the market in the present in favor of the market in the future; it prevents the market in the present from competing for supplies with the market in the future. Furthermore, in the absence of a price control, any build-up of supplies for sale in the future would simply be accompanied by a rise in prices in the present, which would prevent the appearance of a shortage, as we have seen repeatedly in previous discussion.

Finally, it should be realized that the withholding of supplies in anticipation of the repeal of a price control does not imply any kind of antisocial or evil action on the part of the suppliers. Price controls, as we have seen, lead to inadequate stocks of goods; in many cases, it is probable that the build-up of stocks in anticipation of the repeal of controls merely serves to restore stocks to a more normal level. Even if the build-up of stocks does become excessive, its effect later on, when the stocks are sold, is merely to further reduce the free-market price in comparison with what that price would otherwise have been. In any event, all ill-effects that may result are entirely the consequence of price controls.

Rebuttal of the Accusation That Producers Withhold Supplies to "Get Their Price"

The preceding discussion applies to the accusation that producers withhold supplies in order to "get their

price.” This accusation was levelled against the oil companies during the oil crisis and, again, during the natural gas crisis. It will undoubtedly be levelled anew if price controls are imposed in the future.

Once more, the fact is that price controls generally cause sellers to sell too rapidly, and not to hold even normal stocks. Where the anticipation of the controls being removed does lead to the withholding of supplies, the fault is not that of the sellers, but of the existence of controls in the present. It is simply absurd to tell producers that soon they will be permitted to sell at the free-market price while for the present they must pay fines or go to jail if they attempt to sell at as good a price. Responsibility for the withholding of supplies in such a case lies with those who impose price controls and whose support of price controls makes their imposition possible. For no other result can be expected. To blame the producers and the profit motive in such a case is comparable to blaming the rocks and the laws of physics for the damage done by a delinquent who throws the rocks against windows. In acting to make profits, the producers are doing nothing more than acting in accordance with their nature—their *moral* nature as rational beings who wish to live by means of production and exchange.

Although this did not happen in the oil or gas crisis, and is unlikely ever to happen so long as the great majority of businessmen remain ignorant of sound economic theory and lack moral courage, it would be perfectly proper if sellers really did withhold supplies to “get their price”—that is, not merely to take advantage of the higher free-market price they expect to follow the government’s removal of controls, but to withhold supplies *in a deliberate attempt to force repeal of the controls*. Such a withholding would be a kind of strike; more correctly, it would be a refusal to work under conditions of forced labor. By putting an end to price controls, it would be an action in the public interest in the true sense of the term.

It should be realized in connection with this discussion, that in a free market the speculative withholding of supplies is not a means by which sellers can arbitrarily enrich themselves. It is not possible, as widely believed, for sellers arbitrarily to raise prices by withholding supplies and then to sell the supplies they have withheld at the higher prices they themselves have caused. Any attempt to do this would necessarily cause losses to the sellers who tried it. First of all, when these sellers put their supplies back on the market, they would push prices back down by as much as they had first increased them, and in the meanwhile they would have incurred additional costs of storage and have had to forgo the profits or interest they could have earned by selling sooner. In addition, so long as the high prices lasted, other sellers would be encouraged to place on the market whatever

stocks they could spare, so that when the first set of sellers returned to the market they would find their normal market already partly supplied, and thus would end up having to sell at prices lower than they could have received had they not attempted to raise prices in the first place. The only way the speculative withholding of supplies can be profitable in a free market is when it takes advantage of a prospective rise in price that is independently caused, which, of course, means, not caused by the speculators themselves.¹⁰

In the specific case of the oil crisis the withholding of supplies turned out to be entirely mythical. Reports of large numbers of fully loaded tankers standing offshore to “get their price” had no more foundation in fact than the stories about full tank farms and storage depots.¹¹ As concerns the natural gas crisis, the charge was ultimately withdrawn by one of the principal original accusers, President Jimmy Carter’s then Interior Secretary Cecil D. Andrus. According to *The New York Times*, the secretary “said today that a series of studies had produced no evidence that oil companies were withholding natural gas from offshore leases. . . . The interior secretary insisted today that he had had no part in raising those charges and contended instead that they were initially leveled by reporters. . . . Mr. Andrus also made it clear today that the question of withholding was now closed. ‘I’m not going to continue to chase a rabbit,’ he said.”¹²

Price Controls and the “Storage” of Natural Resources in the Ground

Price controls have a particularly destructive effect on the supply of natural resources. Unlike products, natural resources in the ground are imperishable and have zero storage costs. This means that it is possible to consider reserving their use to much more remote periods of the future than is the case with regard to products. The consequence is that under price controls a tendency exists to withhold natural resources from current exploitation even though their current exploitation might be profitable. The reason is that their future exploitation—following the repeal of price controls—is expected to be sufficiently more profitable to justify waiting. In this way, price controls on natural resources act to bring about a twofold restriction of supply: they prevent the development or exploitation of high-cost deposits by making them unprofitable and they postpone the development or exploitation of low-cost deposits by making their development or exploitation in the present less profitable than it will be in the future.

The question may be raised of why price controls would not encourage the more rapid exploitation of low-cost natural resources if the controls were expected to exist permanently. To answer this question, it is only

necessary to realize what “permanently” would have to mean in this context. “Permanently” would have to refer to a period of at least a decade and, more probably, at least a generation. For suppose the effect of a price control is to hold the real value of a resource to half of what it would be in the absence of controls. This means the owners of the resource can look forward to the prospect of a doubling of its real value whenever controls are repealed. Since they incur no storage costs of any kind by waiting, even if they had to wait *twenty-five years* for price controls to be repealed, their gain would work out to something on the order of 3 percent per annum compounded. Such a rate of return, in *real terms* (which means, adjusted for losses in the purchasing power of money), is by no means insignificant in a period of inflation, when it is common for many or most investments to show losses in real terms.¹³ In such conditions, it might pay to wait even for the prospect of a considerably lower positive real rate of return. Of course, if price controls undervalue a resource less severely, the inducement to postpone exploitation is less powerful. But it does not take very much undervaluation to make the owners of the resource prefer to wait five or ten years for the repeal of a control if they have to.

On the basis of these considerations, it is not surprising that the repeal of the price controls on crude oil was followed by a substantial increase in the supply of low-cost oil as well as by additional supplies available only at higher costs.

d. The Supply of Particular Types of Labor and Particular Products of a Factor of Production

A price control reduces supply if it is applied to the wages of any particular occupation or to the wages paid by any particular industry while wages in other occupations or industries are left free. In these cases, the workers in the controlled occupation or industry simply leave to take better-paying jobs at uncontrolled wages elsewhere; and new workers do not enter the occupation or industry. The controlled occupation or industry is made uncompetitive and loses its labor force. For example, if the government were to control just the wages of steel workers, say, the effect would be that steel workers would start going into other industries in response to higher, uncontrolled wages in those industries. Young workers would stop becoming steel workers. Exactly the same would happen if the government controlled just the wages of carpenters, say.

A price control reduces supply whenever it applies to some products of a factor of production, but not to other products of that factor. In this case, the production of the controlled products is curtailed, because it is more profitable to use the factor of production to produce the

uncontrolled products. For example, if the price of milk is controlled, but cheese is not, then the production of cheese will be more profitable than the production of milk. As a result, raw milk will be used more heavily to produce cheese, and less milk will be available for drinking. In other words, the supply of milk for drinking will fall. In view of the continuing popularity of rent control, it is worth pointing out that exactly the same principle applies specifically to apartment houses. Apartment houses can be viewed as a factor of production with multiple possible uses, namely, use as rental housing or use as condominium or cooperative housing. If rent controls are imposed, then landlords will convert their housing to condominiums or co-ops if they are free to do so, because the effect of rent controls is to reduce the profitability of using apartment buildings for rental housing in comparison with that of using them for condominium or cooperative housing. Of course, their decision to do so evokes the same kind of outbursts of self-righteous irresponsibility and irrationalism that we observed a few paragraphs back in connection with the blame heaped on producers for withholding supplies in the face of price controls and the prospect of imminent relief from the price controls.

e. Price Controls and the Prohibition of Supply

Sometimes, the question is raised as to what argument one could give to a consumer to convince him to be against price controls; especially what argument one could give to a tenant to convince him to be against rent controls. Our discussion of how price controls reduce supply indicates a very simple argument to give to any consumer against any price control. This is that if he wants something, he must be willing to pay the necessary price. It is a natural law—a fact of human nature—that a good or service can only be supplied if supplying it is both worthwhile to the suppliers and as worthwhile as any of the alternatives open to them. If the price is controlled below this point, then it is equivalent to a prohibition of supply. To command, for example, that apartments be supplied at rents that do not cover the costs of construction and maintenance, and the going rate of profit, is equivalent to commanding that buildings be built out of impossible materials like air and water rather than steel and concrete. It is to command construction in contradiction of the laws of nature. In the same way, to command that oil be sold less profitably in New York than in Hamburg, say, or that natural gas be sold less profitably in Philadelphia than in Houston, is equivalent to commanding that these materials become drinkable and that water become burnable, for it is no less an act in contradiction of the nature of things.

Now it is simply absurd for a consumer who wants a

good, to support a measure which makes its supply impossible. And that is what one should tell him. That is what the consumers themselves should tell the legislators as soon as the latter become busy trying to enact price control laws for the consumers' alleged benefit. These would-be benefactors of the consumers prohibit the consumers from making it worthwhile for businessmen to supply them. They destroy the businessmen. In doing so, they destroy the consumers' ability to find agents to act on their behalf. Such legislators are capable of reducing the consumers to the point where if they want anything, they will have to produce it themselves, because price controls will make it unprofitable for anyone to supply it to them. Already, rent control has "benefitted" tenants to the point that it is has become increasingly necessary if one wants an apartment to own it oneself: one must buy a "co-op" or a condominium. Price controls made it extremely difficult, and at times absolutely impossible, to buy oil or natural gas. If the legislators go on "benefitting" the consumers long enough with their price controls, they will benefit them all the way back to the economic self-sufficiency that was the leading characteristic of feudalism. They will have destroyed the division of labor.

The Destruction of the Utilities and the Other Regulated Industries

It may be thought that price controls on genuine monopolies, such as government-franchised electric utilities, are an exception to the principle that price controls reduce, indeed, prohibit, supply. In fact, they are not. On the contrary, they have been an excellent illustration of it.

In the absence of inflation these controls are largely without effect, for then they do not actually impose below-market prices. At such times, they are set at a level that, if anything, is almost certainly higher than would have prevailed in a free market. This is the case because they are set high enough to provide the going rate of profit, and then some, to legally protected monopolists, whose costs of production are almost certainly above the costs of production that would prevail in a free market with its legally open competition. But when they exist in conjunction with inflation, the price controls on these monopolies begin to operate as genuine price controls. This occurs because inflation drives up the production costs of the monopolies, while the regulatory authorities either refuse to allow rate increases or allow only insufficient rate increases. In this way, the utilities, and all the other regulated industries, become unprofitable. At first, they merely cease to grow rapidly enough, because their reduced profitability throttles their ability to generate additional capital—that is, they lack the profits to plow back and they lack the profits to provide an incentive to

the investment of sufficient additional outside capital.

When the reduced profitability of these industries is understood to be permanent, or when the policy of the regulatory agencies inflicts actual losses on them in terms of making it impossible for them to replace worn-out equipment at the higher prices caused by inflation, then these industries go into actual decline. They do not have the means of replacement, and their owners withdraw capital to whatever extent they are able in the form of taking dividends.

We are already very far along in this process. Areas such as New York City and much of the state of Florida, for example, have been skirting for many years on the edge of power disasters. Almost every year there is a question of whether generating capacity will be adequate to meet the demand in such places. So-called brownouts, and even blackouts, are not uncommon. Problems of this kind would undoubtedly be far more common and severe if it were not for the relatively depressed state of the American economy in recent years.

The situation of an inadequate supply of power is the result of the restricted profitability of the utilities, caused by price controls. It is compounded, of course, by the ecology movement's policy of harassment of energy producers. Both causes have prevented the construction of sufficient additional generating capacity to keep pace with demand.¹⁴

At the present time, the traditionally regulated industries, such as the electric utilities, the railroads, and telephone service, are the principal victims of price controls, along with rental housing in various towns and cities. Although the situation by and large is probably much improved in comparison with that of the late 1970s, when conditions in these industries appeared more critical—and the oil and natural gas industries were in a state of growing crisis as well, thanks to price controls—these industries are still capable of being destroyed by price controls. And, since the rest of the economic system is vitally dependent on them, their destruction would be disastrous for the entire economy.

Indeed, despite the improvements brought about in the 1980s under the Reagan administration, one must still regard the future with a high degree of pessimism. The public's state of knowledge of economics has not significantly improved. Thus, the causes of the improvements in the situation are not understood. Even those who were responsible for the improvements—through such measures as the repeal of the price controls on oil, the easing of "environmental" restrictions, and the abandonment, at least for the time being, of the policy of accelerating inflation—apparently do not know enough to take credit for their good work, despite the fact that it would be very much to their political advantage to do so. Instead, the

improvements are regarded as essentially accidental and are more or less taken for granted.

Thus, the continued existence even of the remaining price controls holds out the specter of growing power shortages, a disintegrating railroad network, and deteriorating telephone service. The potential for destruction is especially great in the case of electric power, where the effects of price controls are compounded by the actions of the ecology movement. So long as these industries are subject to price controls, and so long as the potential exists for significant inflation, all of these industries are capable of being reduced to the level of rent-controlled housing in the slums of New York City. The only difference will be that if they suffer comparable devastation, they will carry down with them the rest of the economic system. These problems will become apparent if and when a policy of accelerating inflation is resumed.

4. Ignorance and Evasions Concerning Shortages and Price Controls

The fact that price controls are the cause of shortages has been known to all economists at least since the time of Adam Smith. Nevertheless, this elementary knowledge is either unknown or simply evaded by the great majority of today's presumably educated political and intellectual leaders.

These people do not have any idea of the connection between price controls and shortages. In their view, shortages are the result of some kind of physical deficiency in the supply or of an innate excess of needs. They simply do not have any knowledge of the role of price in balancing demand and supply. As a result, it is common to hear them blame shortages on such things as poor crops, an alleged depletion of natural resources, even that old standby the "greed" of consumers. Their level of knowledge is typified by a provision of the rent control law that governed New York City for many years. According to this law, rent controls could not be lifted until the vacancy rate in apartments had first climbed to a certain substantial level. In other words, only when the shortage that rent controls created and maintained was over, could rent controls be lifted.

The same point of view was expressed by a former mayor of New York, Abraham Beame, when still in office. When asked to comment on an economic regeneration plan for New York City that had urged the repeal of rent control, he "refused to endorse the rent control proposal, saying, 'we still have a vacancy rate of less than 5 percent and we still have a housing shortage.'"¹⁵

To find a parallel for this kind of reasoning, one would have to find a badly overweight person, say, who was

firmly resolved to go on a diet just as soon as he lost twenty pounds, or an alcoholic who was firmly resolved to stop drinking just as soon as he sobered up. Of course, these are not perfect analogies, because the overweight person and the alcoholic at least know the causal connections and are evading them. In the case of the government officials and the intellectuals responsible for rent control, most of them do not even know the causal connection. They are too ignorant even to be guilty of evasion in this particular instance.

The confusion of our public officials extends to the point that when they are confronted with the fact that the repeal of a price control would actually end a shortage, they then deny the very reality of the shortage: they view the shortage as "artificial" or "contrived." For example, during the natural gas crisis the then Governor of Pennsylvania, Milton Schapp, declared before television news cameras that if price controls were lifted and the gas shortage came to an end through the appearance of additional supplies, the very appearance of the additional supplies would prove that the shortage had been "contrived." The governor simply did not know that a higher price increases supply by enabling a local market successfully to compete for supplies with other markets, and, of course, that it leads to an expansion of the total supply by making production more profitable. He also did not know that the supply available for vital purposes can be increased by enabling those purposes to out-compete marginal purposes, and that the elimination of shortages eliminates the need to hoard supplies, which supplies then also appear on the market.

Inflation and the Appearance of High Profits

In an important respect, the ignorance that surrounds the effect of price controls is made possible by the fact that inflation raises the apparent or, as economists say, the nominal rate of profit that businesses earn. It does not increase the real rate of profit—the rate in terms of the actual physical wealth that business firms gain—in fact, quite the contrary), but it does increase the rate of profit expressed in terms of the depreciating paper money.

To understand what is involved, it must be realized that the costs which enter into the profit computations of business firms are necessarily "historical"—that is, the outlays of money they represent are made prior to the sale of the products. This follows from the fact that production always takes place over a period of time. Materials and labor must usually be bought weeks or months before the resulting products are ready for sale, and sometimes even further in advance. Machinery and factory buildings are bought many years, even decades, before their contribution to production comes to an end. Thus the costs of business enterprises in producing their

products represent outlays of money made weeks, months, years, or even decades earlier.

Now to whatever extent inflation occurs, the sales revenues of business firms are automatically increased: the greater spending that inflation makes possible is simultaneously greater sales revenues to all the business firms that receive it. Since costs reflect the given outlays of earlier periods of time, the increase in sales revenues caused by inflation necessarily adds a corresponding amount to profits.

A slightly different way to grasp the same basic idea is to realize that the total outlays business firms make for productive purposes at any given time are a reflection of the quantity of money in existence at that time, while the sales revenues they will subsequently take in for the products resulting from those outlays, will be a reflection of the quantity of money in existence later on. It follows that the more rapidly the quantity of money grows, the greater must be the ratio of sales revenues to costs of production and to capital previously invested. This, of course, implies a corresponding rise in the general rate of profit on capital previously invested. The rate of profit in the economy is raised to progressively higher levels the more rapidly the quantity of money, spending, and sales revenues rise.

It cannot be stressed too strongly, however, that the rate of profit that rises is purely nominal, that is, it is strictly in terms of money. All that is happening is that the more rapidly money is increased, the faster is the rate at which *money* is gained. If there are different monies, increasing at different rates, then the nominal rate of profit is higher in the monies that increase more rapidly. For example, it is higher today in U.S. dollars than in Swiss francs, and higher in Argentine pesos than in U.S. dollars. (The same principle and example apply to interest rates, since the most important determinant of interest rates is the rate of profit that can be earned by investing borrowed money in business.)

The rise in the nominal rate of profit does not imply any increase in the *real* rate of profit, that is, the rate of gain in actual wealth, because the same rise in spending that raises sales revenues and profits in the economy also raises the level of prices. The extra profits are almost all necessary to meet higher replacement costs of inventory and plant and equipment, and the rest are necessary to meet the higher prices of consumers' goods that the owners of businesses were previously able to buy in their capacity, say, as stockholders receiving dividends. Indeed, the real rate of profit firms earn actually *falls* while the nominal rate of profit rises. One major reason it does so is because the additional nominal profits, while mainly necessary for the replacement of assets at higher prices, are *taxed*, as though they were real profits. Thus firms

are placed in a position in which, after paying taxes, they are actually worse off as the result of the rise in the nominal rate of profit.

A good illustration of these facts is the case of a hypothetical merchant who normally buys \$100 worth of goods on January 1 and sells them at the end of the year for \$110. If a rapidly increasing quantity of money increases total spending in the economy by 10 percent over the year, this merchant will tend to sell his goods for \$121 instead of \$110, that is, also by 10 percent more. Consequently, his nominal profit will be increased from \$10 to \$21. However, the same increase in the quantity of money and volume of spending that enlarges our merchant's sales revenues and profit also raises the replacement cost of his inventory. Instead of being able to replace his inventory for \$100, as he was able to do in the past, he will now have to replace it at a cost of \$110. Thus, the whole increase in the merchant's profit is purely nominal, not real. While his profit rises from \$10 to \$21, fully \$10 of this additional profit is required merely to replace inventory at higher prices. This leaves the merchant with \$11 that he can use for other purposes. But these \$11 will probably buy no more than \$10 used to buy, because the increase in the quantity of money and volume of spending has probably raised the prices of the things the merchant can buy outside of his business. Thus, the \$21 profit the merchant now has represents no more in terms of actual wealth and ability to buy goods than the \$10 profit he used to have.

Indeed, as I have said, our merchant will actually be *worse off* as a result of his higher nominal profit. Because, apart from other reasons that will be presented later in this book, he must pay additional taxes on the additional nominal profit, and must restrict his consumption or new investment in order to do so.¹⁶ To understand this point, assume a tax rate of 50 percent on profits. Thus, initially, when our merchant made \$10 in profit, he paid \$5 in taxes and had \$5 left to himself, which he could either consume or add to his business. When his profit rises to \$21, his taxes rise to \$10.50. Of the \$10.50 left over, fully \$10 are required to replace inventory at higher prices. Therefore, the merchant is left with a mere 50¢ that he can consume or use to expand his business, whereas he initially had \$5, and at a lower level of prices as well.

Exactly the same principles as apply to the profit of our hypothetical merchant apply to the profits of all real-life merchants, and to the profits of businessmen in general, because the same kind of increase in nominal profits as occurs on inventories also occurs in the case of depreciable assets, such as buildings and machinery.¹⁷

It is in this light that the consequences of the attitude that profits are "too high" must be considered. The fact

is that in the context of inflation the seemingly high rates of profit that firms earn represent a decline in real profits and, quite possibly, the total elimination of real profits. In such circumstances, to argue that because a rate of profit is high by historical standards it is high in any meaningful sense, is to display the utmost ignorance. To limit an industry's profits in any way in such circumstances is simply to invite its destruction.

But precisely that is what is being done or has been done to the electric utilities, the railroads, the telephone companies, and the oil and natural gas industries. And it is what has been done to the rental housing industry in New York City for over half a century. For many years, for example, the government of New York City was proud of the fact that it guaranteed to landlords under rent control the right to earn a 6 percent rate of return on their initial investments, made, in most cases, before World War II. Six percent, reasoned the city officials, was a "fair" rate of return. What honest landlord could want more? The city officials neglected the fact that since the landlords' original investments were made, replacement costs had increased many times over and that a 6 percent return on the construction costs of decades earlier had to represent a disastrously losing proposition.

Amazingly, when landlords began to stop keeping up their properties as a result of such loss-making conditions, *they* were the ones accused of "milking" their properties—as though the city or the tenants had originally constructed the buildings and the landlords were now trying to squeeze out of them whatever they could. (And then, as punishment, the city refused to grant rent increases even when called for by its own criterion of providing a 6 percent return.) The simple truth is that the city government of New York, with the support and participation of hundreds of thousands of ignorant tenants, has milked the rental housing industry to the point of virtually totally destroying it. Today, in New York City, the point has been reached where if one wishes a place to live, one must buy it. As already pointed out, the same fate may well be in store for other, more important industries in this country that labor under price controls.

The Destructionist Mentality

What is at root in these cases of wholesale industrial destruction is not ignorance alone, but a mentality that makes itself ignorant. It is a mentality that shows up in the cavalier assumption that the problems an industry experiences as the result of price controls, rising costs, mounting taxes, and harassment by the ecology movement are all somehow the result of "its own inefficiency." This mentality is unaware that inefficiency is itself an inevitable consequence of government interference. If an industry is deprived of the prospect of profits, if its

operations are encumbered with endless bureaucratic regulations, then it has no incentive or even possibility to be efficient.¹⁸ It is absurd to blame an industry's inefficiency on anything but government interference; in a free economy, profit and loss incentives and the freedom of competition operate steadily to increase efficiency.

The ignorance that underlies the destruction of our economic system is made possible by a protective shell of envy and resentment. People take the attitude that somehow the utilities, the landlords, the oil industry, or whoever, are "already rich enough," and that they'll be damned if they'll let them get any richer. So, on with the price controls. That is the beginning and the end of their thinking on the subject, and they just don't care to think any further. They are eager to accept high nominal profits as a confirmation of their view that the industries concerned are "rich enough," and to let it go at that.

However, the simple fact is that none of these industries is rich enough, and in preventing them from becoming richer, or even staying as rich as they are, people foolishly harm themselves. None of these industries is rich enough for the simple reason that we really do not have enough power plants, enough good apartment buildings, or enough oil wells and oil refineries. Speaking for myself, *as a consumer*, I must say that I would like the power companies, the landlords of New York City, the oil industry, and so on, all to be worth many more billions than they are presently worth. I would benefit from that fact. If the utilities had more power plants, my supply of electricity would be better assured and I would not be subject to the power interruptions that I am now subject to. If the landlords of New York City had more and better buildings, tenants and possible prospective tenants, such as myself, would be able to have a better apartment. If the oil industry had more wells and refineries, I would have a more abundant and secure supply of oil products.

If one thinks about it, I believe, nothing could be more absurd than consumers in a capitalist economy attacking the wealth of their suppliers. That wealth serves *them*—they are the physical beneficiaries of it. All of the wealth of the utilities, the landlords, the oil companies—where is it? It is in power plants and power lines, apartment buildings, oil wells and oil refineries. And whom does it actually, physically, serve? It serves the consumers. It serves *us*—all of us. We have a selfish interest in the preservation and increase of that wealth. If we deprive an electric utility of a power plant, we deprive ourselves of power. If we deprive our landlords of more and better buildings, we deprive ourselves of apartments. If we deprive the oil industry of wells and refineries, we deprive ourselves of gasoline and heating oil.

This harmony of interests between the consumer and

the producer under capitalism is one of the great, profound insights of von Mises.¹⁹ Because of it, even if businessmen become cowardly and do not fight for their own interests, we, as consumers, must fight for them, and thereby for ourselves. For we have a selfish interest in being able to pay prices that make it profitable for businessmen to supply us. It is to our self-interest to pay utility rates, rents, oil prices, and so on, that enable the producers in these fields to keep their facilities intact and growing, and that make them want to supply us. And I must say, in view of the principles we have already learned, that we do not have to worry about being charged unfairly in a free market, because any high profits that might be made from us are simply the incentive and the means to an expanded supply, and are generally made only because of special efficiency on the part of the producers who earn them.

A Defense of Inventory Repricing

In early 1974, when inflation was proceeding more rapidly than now, supermarkets began to raise the prices of the goods already on their shelves, which had initially been marked with lower prices. Because the stores had purchased those goods at prices which had not yet risen, it was assumed that it was some kind of monstrous injustice for them to charge higher prices. The higher prices, it was argued, merely bloated the profits of the supermarkets and were the cause of a higher cost of living for consumers.

What those who spread this argument chose to ignore was that the *replacement* costs of the merchandise had risen and that if the supermarkets had not raised their prices, they would not have had the means of replacing their inventories. They would have been in exactly the same position as our hypothetical merchant if he had not raised his prices.²⁰ Assume that our merchant held to his old prices and thus continued to take in only \$110, while his replacement cost rose from \$100 to \$110. His nominal profit that year, based on historical cost, would have remained at \$10 and, after paying taxes, he would still have had \$5. The only problem would have been that even if he allowed absolutely no dividend for his own consumption, he would have had no more than \$105 available for replacing his inventory, while the sum he required for replacement was \$110. He would have had to reduce the size of his operations. Exactly this would have been the position of the supermarkets if they had been unable to raise their prices in anticipation of higher replacement costs.

It follows that the consumers who wanted cheap goods at the supermarkets' expense would have gotten fewer goods and, if this process were kept up long enough, eventually no goods at all. And, paradoxically, at what-

ever point the control on the nominal rate of profit was finally abandoned, they would have had to pay higher prices than if the control had never been imposed, because prices would then have had to rise on the basis of a decrease in supply as well as on the basis of an inflation-caused increase in demand.

In confirmation of the fact that little or nothing has been learned since 1974, the identical line of argument was raised against the oil companies in the fall of 1990, when they increased the prices of their refined products on the basis of the sharply higher current price of crude oil, which had been caused by Iraq's invasion of Kuwait. Fortunately, the critics were not able to impose price controls on the oil industry in 1990, as they had in 1971.

The Campaign Against the Profits of the Oil Companies

In early 1974, every release of a quarterly earnings report by an oil company was an occasion for *The New York Times* to run a story headlined as a staggering increase in oil company profits. Day after day, one would read a headline in that newspaper that the profits of oil company X were up 60 or 70 percent or more over the same quarter the year before. This rise in profits was constantly mentioned in conjunction with the rise in the price of gasoline and other petroleum products, which had also risen on the order of 60 or 70 percent over the same period of time. It was constantly implied—by *The New York Times*, by *Time* magazine, and by a host of television news commentators—that the rise in oil company profits was responsible for the rise in the price of oil products. And because the rise in these prices was presented as the cause of practically the whole problem of inflation, the impression was created that the oil companies were out to destroy the country with their insatiable greed for profits. By the same token, of course, the oil companies were depicted as eminently deserving to be throttled with price controls.

The evasions, distortions, and misrepresentations in this case were enormous. I think they are worth going into because they are a classic illustration of how the supporters of price controls argue and what they are capable of.

First of all, the supporters of controls evaded two facts that should have been known to everyone: They evaded the fact that the rise in the price of oil products in the United States was the result of a rise in the world price of crude oil brought about by the Arab embargo and the Arab-sponsored cartel, that is, that it was the result of a rise in the oil companies' *costs* of obtaining imported oil. In addition, they evaded the fact that since August of 1971 the prices of oil and oil products produced or sold in the United States had been totally controlled by the

U.S. government, and were currently controlled at levels far below the world-market prices of these goods; indeed, at levels which, until the end of the crisis period, did not even allow the oil companies to pass on more than a part of the higher cost of imported oil. The truth is that our price controls made the importation of foreign oil highly *unprofitable*, which is one of the major reasons we suffered from a shortage of oil at the time. Furthermore, while *The New York Times* and the other news media were spewing headlines about the enormous rise in oil company profits, they neglected to mention that the profits of the oil companies on oil production within the United States increased only on the order of about 6 percent during the crisis period. This was in line with the increase in the physical volume of domestic production in the period. Profits on domestic production did not and could not have increased any more than that because the selling prices of the oil companies were all rigidly controlled by the government, in line with their costs of production.

The real facts, therefore, are that during the oil crisis the American market was a very unprofitable market for the importation of foreign oil and a not very profitable market for the production of domestic oil or oil products. Nevertheless, the news media constantly pointed to a sharp rise in oil company profits and claimed that it was responsible for the rise in prices.

To be sure, there was a substantial increase in oil company profits *on a percentage basis*. Technically, the media were correct in reporting profit increases of 60 and 70 percent or more. But in representing these profit increases as the cause of higher American oil prices, the media committed four distinct acts of dishonesty or misrepresentation.

First, the media neglected to inform the public that these higher profits were not earned on the production or sale of oil or oil products *in the United States*. In many cases, over half the rise in profits came from inventory profits on stocks of oil and oil products held abroad, where price controls did not apply, and from profits on foreign-exchange holdings. The inventory profits were the same in principle as the jump in profits of our hypothetical merchant or of the supermarkets that raised prices in anticipation of higher replacement costs. These inventory profits earned abroad reflected nothing more than that the oil companies possessed some inventories acquired before the rise in the world-market price of crude oil, and were able to sell the inventories at the higher prices corresponding to the higher replacement price of crude oil. The extra profits earned on the inventories merely served to enable the oil companies to maintain their level of operations, just as was the case with the supermarkets.

The profits on foreign-exchange holdings were similar. The oil companies are largely international and hold such currencies as Swiss francs and German marks, as well as U.S. dollars. During the oil crisis, the price of the dollar fell in terms of these currencies. This meant that the francs and marks held by the oil companies were suddenly equivalent to a larger number of U.S. dollars. This increase in the dollar value of their foreign-exchange holdings was included in the reported profit gains of the oil companies.

The rest of the increase in oil company profits was the result of higher profits on foreign operations other than profits on inventory or currency holdings, and higher profits on other lines of business, such as the chemical business, in which a number of oil companies were involved and which had a good year at the time. All of these facts about the sources of higher profits were simply ignored.

The second dishonesty of the media was that they did not point out that even with the 60 or 70 percent increase—from whatever sources—the profits of the oil companies were only restored to the same level in relation to sales revenues at which they had existed in 1968. It was not pointed out that the intervening years had been poor ones for the oil industry and that the sharp percentage increase in its profits was largely the result of measuring the increase against an unusually low base. I remember one case in particular, in which the headline in *The New York Times* blared “2-Month Earnings Soar at Occidental.”²¹ It turned out, if one read the article very, very carefully, and did some arithmetic that the reporter and the editor had apparently not bothered to do, that the soaring earnings represented an increase in profits from about *seven-tenths of 1 percent of sales revenues to about 5½ percent of sales revenues*, which latter figure was still below normal for the oil industry in previous years. Of course, with this type of misrepresentation, it would be possible to write headlines about infinite increases in profits. All one would need would be to find firms that earned some profits in the current period but which had earned zero profits or incurred losses in the period with which it was compared. The percentage increase would be infinite.

Closely related to this kind of dishonesty was a further misrepresentation. In all of the countless times that the news media mentioned 60 to 70 percent increases in profits in conjunction with 60 or 70 percent increases in product prices in the petroleum industry, they never once, to my knowledge, mentioned that profits are only a small percentage of prices—5 percent, 10 percent, rarely much more than 10 percent. This applies both to the petroleum industry and to practically every other industry. Accordingly, it was never pointed out that any given percentage

increase in profits must necessarily represent a much smaller percentage increase in prices. If profits are initially 10 percent of a price, a 70 percent increase in profits does not equal a 70 percent increase in price, but only a 7 percent increase in price. If, as in the case I mentioned, profits are initially seven-tenths of 1 percent of the price, even a 1,000 percent increase in profits would not mean some kind of fantastic increase in price, but a rise merely on the order of a few percent. Thus, even if the oil companies had earned their higher profits in the United States, which they did not, and even if those higher profits had been the cause of a rise in oil prices, which they were not, they could not have been of any significance as a cause of higher oil prices. Nevertheless, by the news media's constant conjunction of their roughly equivalent percentage increases, it was made to appear that the rise in profits of the petroleum industry is what accounted for the rise in the prices of petroleum products.

Finally, just as the media regularly associated the percentage increases in profits with the percentage increase in the price of oil products, they just as studiously avoided ever mentioning the rate of profit on capital in connection with the rise in the consumer price index. Such a connection would have shown that the oil industry was far from being very profitable in real terms. The reasons are as follows. During the oil crisis, the consumer price level was rising at an annual rate of 13 percent, while the United States' most profitable, most successful major oil company was earning only 18 percent a year on its capital. This meant that while \$100 invested in that company would grow to \$118 in a year, it would take \$113 at the end of the year to buy what the \$100 had bought at the beginning of the year. This meant that the real rate of gain of the owners of that company was less than 5 percent a year—it was \$5 divided by \$113. A real rate of profit of less than 5 percent for the country's most profitable, most successful major oil company is quite low. And, of course, most oil companies were earning substantially lower real rates of profit. Any oil company whose nominal rate of profit was below 13 percent, say, 8, 10, or 12 percent, was actually losing money in real terms! But, as I say, one never found the media dealing with the real rate of return of the oil companies.

It may be asked where I obtained my knowledge of the facts I have cited. The answer, strangely enough, is the general news media themselves, especially *The New York Times*. The facts appeared there. They simply received no stress, or they weren't integrated. They were buried in a mass of articles whose headlines and general tenor created exactly the opposite impression. Or they appeared at different times, in different stories. For example, as I have indicated, figures were reported showing dollar totals of profits and sales revenues; it was

simply left to the reader to perform the necessary long division in order to compute profits as a percentage of sales revenues. Likewise, while the percentage increase in profits over the previous year was carried in headlines, only occasionally, in an almost offhand reference, would one find a mention of the actual nominal rate of profit on capital invested. And, while the rate of increase in the consumer price level was featured prominently, it was never mentioned in connection with nominal profit rates, so that one would know what to make of those rates.

One would also read statements, buried deep in articles denouncing oil company profits, that, according to oil company officials or other sources, the rise in profits was largely the result of inventory profits earned abroad and gains on foreign-exchange holdings. The statements were never disputed. They were simply ignored, as being of no significance. And, of course, it was certainly reported in the press that all of the prices charged by the oil companies were controlled by the government and that the Arabs had brought about a radical increase in the world price of crude oil, which, of course, meant higher costs to the oil companies. Yet, these two facts of fixed prices and radically higher costs, facts which were obviously incompatible with the oil industry being very profitable, were simply ignored in the articles reporting the profit increases, as I pointed out earlier.

The kind of distortions committed in the media's treatment of the profits of the oil companies will almost certainly be committed in the future, in attempts to impose or continue controls on other industries. The reader should be on guard against them and should hold in mind, in addition to the need for nominal profits to allow for the replacement of assets at higher prices, such further important matters as the source of the alleged profits under attack, their size in relation to sales revenues, the basis of comparison used in showing their change, and the relation between percentage changes in them and percentage changes in selling prices.

In connection with the distortions present in recent attempts—that is, in 1992 and 1993—to blame the sharp rise in the cost of medical care over the last decades on the high profits made on a few patented drugs, the reader should also keep in mind the substantial losses incurred in the numerous unsuccessful research and development efforts that take place. He should also realize that the attacks made on the large size of the pharmaceutical companies' outlays for advertising and promotion ignore the fact that much of the outlays for promotion represent the distribution of large quantities of free samples of new medications to physicians, who in turn give the samples to their patients without charge. Thus, alongside the accusation that the pharmaceutical industry charges too much for its products, this accusation turns out to repre-

sent an attack on the pharmaceutical industry for giving away too many of its products for free. Finally, the reader should realize that the attacks made on the pharmaceutical industry for spending large sums on the development of new drugs that do the same job as already existing drugs sold by other firms, represent the contradiction of attacking the industry both for the high profits to be made from successful drugs and for the competitive quest that serves to bring those high profits down by means of others being able to offer competing alternatives. Such attacks are attacks on the very nature of the profit system.

How the U.S. Government, Not the Oil Companies, Caused the Oil Shortage

Let us try to keep in mind all that we have learned about shortages, and look further at the ignorance and evasions displayed during the oil shortage. I am concentrating on the oil shortage because it had such a dramatic effect on practically everyone in the United States and is so illustrative of all of the problems associated with price controls, including the kind of inappropriate mental attitudes that are connected with them.

There were two very popular explanations of the oil shortage that went around at the time, both of which tried to blame it on the oil companies rather than on price controls. According to one of these explanations, the oil companies had created the shortage in order to be able to obtain permission to build the Alaskan oil pipeline, which had been delayed for many years by the lawsuits of the ecology movement. According to the second explanation, the oil companies had created the shortage in order to eliminate the independent gas stations, to which they were reportedly observed denying supplies.

The first observation which must be made against both of these claims is that they do not see that shortages can result only from a price that is too low and must disappear as the price rises. To repeat once again, no matter how physically limited is the supply of a good or how urgent the demand for it, no shortage can possibly exist at the price established in a free market. For the free-market price will be high enough to level the quantity of the good demanded down to equality with the supply that exists—all the while, of course, acting to expand the supply that exists. Even if one could establish—which one certainly cannot—that the oil companies had conspired to reduce the supply of oil, still, one could not blame them for the shortage. Had they reduced the supply of oil, they would have sold it at a higher price, and at the higher price there would have been no shortage. In order to blame the oil companies for the *shortage*, one would have to show that the oil companies *deliberately charged too low a price for their oil*. That would be the only conceivable way that they could have caused the

shortage. But that is absolutely absurd. It was not the oil companies that were responsible for too low a price, but the government, with its price controls. The government stood ready to fine or possibly even imprison anyone selling oil or oil products at prices that would have eliminated the shortage.

The interests of justice, however, require that I show not only that the oil companies could not have caused the shortage, but also that they were not responsible for anything acting to raise the price of oil in the absence of price controls.

Observe. The oil companies were not responsible for the nationwide and worldwide increase in aggregate demand that acted to drive up all prices, including, of course, the price of oil. Nor were the oil companies responsible for any decrease in the world supply of oil. Both were exclusively the result of government actions. All governments, that of the United States included, were and are bent on reckless expansions of the money supply that act to raise the demand for everything and the price of everything. And it was governments that were responsible for the restriction in the supply of oil—not only the governments that are members of the international oil cartel or that participated in the Arab embargo, but also the U.S. government.

The U.S. government, acting largely under the influence of the ecology movement, restricted the supply of oil in the following ways: (1) It prevented exploration for and development of oil reserves in vast areas of territory arbitrarily set aside as “wildlife preserves” or “wilderness areas.” It even delayed the development of the vital North Slope Alaskan oil fields for many years, on the grounds of alleged concerns over the “environmental” effects of the pipeline required to transport the oil to Alaska’s south coast. (2) It prevented the development of offshore wells on the continental shelf. (3) It prevented the construction of other oil and gas pipelines, of new refineries, oil storage facilities, and facilities for handling supertankers. Where it did not totally prohibit these activities, it greatly increased their cost by creating enormous delays—a policy that was enthusiastically joined by the other levels of government. (For example, the plan for an oil pipeline from Southern California to Texas was abandoned, with a loss of over fifty million dollars, because the necessary permissions could not be obtained from the more than *seven hundred and fifty* federal, state, and local government agencies involved.) (4) The U.S. government imposed price controls on oil. (5) It acted further to restrict oil company profits, and thus oil industry investment, by punitively increasing their rate of taxation through first reducing and then totally abolishing the customary depletion allowance on crude oil. (6) It deterred investment in the oil industry through threats of

antitrust actions forcing the breakup of existing companies, and through threats of nationalization.

In addition, the U.S. government was responsible for an enormous artificial increase in the demand for oil, over and above the increase caused by its policy of inflation. It caused this artificial increase in demand in the following ways: (1) Since the mid-1960s, it controlled the price of natural gas, thereby undermining the growth of that industry. The demand for fuel that normally would have been supplied by natural gas therefore overflowed largely into an expanded demand for petroleum, which is its closest substitute for most purposes. (2) Under the influence of the ecology movement, the government prevented the construction of atomic power plants and restricted the mining of coal, policies which it continues to pursue. In these ways too, it forced, and continues to force, the demand for fuel to rely more heavily than necessary on oil supplies. (3) Again under the influence of the ecology movement, the government forced electric utilities to shift from the burning of coal to the burning of oil and it forced automobile manufacturers to produce engines requiring far higher gasoline consumption per ton-mile.²²

In sum, the government and the ecology movement have done everything in their power to raise the demand for and restrict the supply of oil.

It should be realized that it was only these actions of the U.S. government that made possible the dramatic rise in the price of oil. The U.S. government bears a far greater responsibility than the Arab cartel. *It* is the party that made it possible for the cartel to succeed. All that the cartel did was to take advantage of the artificial increase in demand and restriction of supply brought about by the U.S. government. Had the U.S. government not restricted the expansion of the domestic petroleum industry and forced up the demand for oil, the supply reductions carried out by the cartel would not have had such a significant effect on the price. Because in that case, such supply reductions would have been at the expense of far less important wants than actually turned out to be the case. With the larger domestic supply of oil and competing fuels that a free market would have produced, the marginal utility of any given amount of oil would have been far less. The loss of any given amount of oil by virtue of the supply reductions carried out by the cartel would therefore have been much less serious. As a result, the cartel would not have been able to raise the price nearly as much by virtue of any given amount of supply reduction. In such circumstances the cartel members would probably not have found it worthwhile to reduce the supply at all. In order to achieve a rise in the price of crude oil of the magnitude that actually occurred, the cartel members would have had to reduce their own

production over and above the amount by which they actually did reduce it, by a further amount equal to the sum of the reduced supply and increased demand for oil caused by the policies of the U.S. government.

Furthermore, in the absence of our price controls, any rise in the price of oil achieved by the cartel would have worked to the advantage of the American oil industry at the expense of the oil industry in the countries belonging to the cartel. This alone would have been enough to frustrate the plans of the cartel. For in this case, the effect of the cartel's restriction of supply would have been to hand the American oil industry the profits and the capital required for an expansion of supply. The cartel would then either have had to allow the price of oil to fall or else it would have had to restrict its own production still further, which would have meant that the American oil companies would have earned the high price of oil on a larger volume of production and have had still greater profits available for expansion, thereby creating still worse problems for the cartel in the future.

It should be obvious that it is impossible for any cartel to succeed that is confronted with a major competitor able to profit from its policies and expand his production. The Arab cartel was able to succeed only because the U.S. government did its utmost to prevent the cartel's competition—the U.S. oil industry—from earning high profits and expanding. Although it was certainly not their intent, in imposing and then perpetuating price controls on oil and oil products, a majority of the highest elected officials in the United States—three presidents (from Nixon to Carter) and a majority of the members of the U.S. House and Senate during those three administrations—behaved as though they owed their election to voters in the member countries of the Arab cartel—as though they were elected in places like Saudi Arabia and Iran rather than in states and districts within the United States. For it was certainly not an American constituency that their actions served, but the interests of the Arab cartel.

In the absence of the U.S. government's destructionist policies, the Arab cartel would probably never even have been formed in the first place, because the conditions required for its success would have been totally lacking. It is not accidental that following the repeal of our price controls on oil in 1981 and the easing of price controls on natural gas and the "ecological" restrictions on the development of oil reserves, the price of oil dramatically declined, despite all efforts to prevent it on the part of the OPEC cartel. If the United States were to abolish all the remaining controls on the production of energy, the OPEC cartel would be completely broken, and the real price of energy would resume the descent it enjoyed from the start of the Industrial Revolution until the enactment

of price controls in 1971. Such a policy, of course, would entail removing the prohibitions on the construction of atomic power plants and the restrictions on the strip mining of coal. It would also entail the privatization of the vast landholdings of the federal and state governments in Alaska and the other Western states and of the continental shelf, so that oil and gas reserves could be freely developed.

In sharpest contrast to the actions of the U.S. government, at every step of the way the oil companies sought, and have continued to seek, to expand the production of crude oil and oil products in order to keep pace with the growing demand for oil. They have consistently sought to develop new sources of supply, such as the Alaskan and offshore fields, and to construct new refineries and improved harbor facilities. In other words, they have done everything in their power to keep the price of oil and oil products as low as economically possible. Any other policy would have been against their interests.

This last point must be stressed. In a free market, the oil companies' *profit motive* is tied to achieving as great a supply and as low a price as possible. Consider first the interests of the firms that are predominantly petroleum refiners. Their capital is invested primarily in refineries, pipelines, tankers, delivery trucks, and the like, rather than in deposits of crude oil in the ground. These firms clearly have an interest in the greatest possible supply and lowest possible price of crude oil. For the price of crude oil is their *cost*. These firms have the same interest in an abundant supply and low price of crude oil that every producer has in an abundant supply and low price of his raw material.

By the same token, consider the interests of the producers of crude oil. Their interests lie with the greatest possible efficiency of refining operations and the lowest possible price of refined petroleum products. Because the lower the prices of refined products, the greater the quantity of them demanded and therefore the greater the quantity demanded of crude oil: the price of crude oil can benefit by part of any cost savings in refining. This mutual tension between the interest of refiners and producers of crude oil makes it necessary for each group to try to improve its own production. If the existing producers of crude oil lag behind, they can expect competition from the refiners, who can develop their own supplies of crude oil or expand their existing crude oil operations. If the existing refiners lag behind, they can expect competition from the producers of crude oil, who, for their part, can undertake refining operations or expand their existing refining operations.

In addition, both groups can expect competition from total outsiders if they fail to exploit any significant opportunity for improvement. And, of course, within each

group, whichever individual firm succeeds in improving production ahead of its rivals will almost certainly gain at their expense. For example, if one particular refiner improves his efficiency and cuts his costs, he will have higher profits and will thus be able to accumulate additional capital. It will almost certainly pay him to use his additional capital to expand his production, and to create a market for his additional production by lowering his prices. His lower costs will still enable him to have high profits even at lower prices, and his lower prices will both attract new customers to the industry and take away some customers from rivals who cannot afford to sell at such low prices. Exactly the same considerations, of course, apply to the producers of crude oil.

For these reasons, it was no accident, but logically necessary, that the oil companies have all along sought to expand their production. It was the operation of these very principles that brought the oil industry into existence in the first place and developed it from virtually nothing into the productive giant it later became and still is today.

To argue, therefore, that the oil companies were responsible for the oil shortage is an absurdity compounded by a triple injustice. It is an absurdity in that, as we have seen, it implicitly accuses the oil companies of charging too low a price for their oil. This is something they would never do. And the critics of the oil companies, who constantly accuse them of seeking to charge prices that are too high, should have a sufficient respect for logic not to accuse them simultaneously of causing shortages by charging prices that are too low. (Of course, the critics do not know that they are guilty of a contradiction, because they have no idea either of what causes shortages or what determines the price of oil.) The accusation embodies a triple injustice in that it evades: (1) the fact that it was the government's price controls that kept the price too low and so created the shortage, (2) the fact that the government and the ecology movement did practically everything they could to restrict the supply and expand the demand for oil, and (3) the fact that by the nature of the profit motive the oil companies have always worked to expand the supply of oil and reduce its price.

To argue in addition that the oil companies created the shortage for the purpose of being able to build the Alaskan pipeline is to pile on still further absurdities. The obvious truth—given the price controls—is that the construction of the pipeline would have mitigated the shortage somewhat, had it not been so long delayed. To argue that its construction was the *motive* for the shortage is not only to display the utmost ignorance about the causation of shortages and callous indifference to the most elementary questions of justice, it is also to display a lack of comprehension of the law of causality in relation to the

physical world. Because according to this argument, the pipeline was something that only the oil companies wanted; the consumers of oil products, allegedly, could have gotten along quite well without the pipeline. Oil products, according to the mentality behind this argument, simply come from oil companies. The oil companies, it is believed, are perfectly capable of producing oil products without oil fields or oil pipelines. The oil companies desire oil fields and oil pipelines, one gets the impression, not because they are necessary to production—production is causeless—but in order to disturb the caribou and the grizzly bears and to pollute the air.

This denial of the elementary physical connection between products and the means of producing them, I must point out, is not an isolated phenomenon confined to the arguments about the Alaskan oil pipeline. It is simply a further manifestation of the same mentality we have already encountered in consumers who denounce the wealth of their suppliers—consumers who will be damned if they'll let the utility that supplies them own the power plants necessary to do so, or their landlord own a decent building. This mentality pervades the whole ecology movement. It is the mentality of all of its members insofar as they both prevent the development of energy supplies and denounce the producers of energy for not producing enough.²³

Let us turn to the second version of the argument that the oil companies were responsible for the shortage: the claim that they created it for the purpose of eliminating the independent gas stations by denying them supplies.

It may very well be the case that the oil companies did cut off or discriminatorily reduce supplies to the independents, as widely reported. My own personal experience does not confirm this, but I am willing to believe it—not because it was reported in the press, but because it would have been a logical consequence of the shortage. Given the existence of the oil shortage, every oil company that owned gas stations had the following choice: either it could reduce supplies to its own gas stations, where its own capital was invested and stood to suffer loss if the stations had to close or restrict operations; or it could reduce supplies to gas stations owned by others, where it was other people's capital that was invested and would suffer loss. Naturally, if an oil company—or anyone else—is confronted with the choice of having to lose its own capital as a result of some absurd government action, or allowing the loss to fall on the capital of someone else, it will choose the latter. And there is no moral reason why it should not. It is no one's moral obligation to offer up his wealth to the government's destructionist policy so that he may suffer his "fair share" of the damage it inflicts.

I must point out that if it were not for the controls and the shortage, the oil companies and the independents would have enjoyed a perfectly harmonious, mutually profitable relationship, as they always did in all the years before the controls and the shortage. An oil company *benefits* from the existence of independent stations willing to sell its gasoline, and has absolutely no reason to try to undermine them, but every reason to try to promote them. Its benefit is that it can sell more gasoline without having to supply the capital necessary to buy or build gas stations. Even if the oil company owns some of its own gas stations, it still benefits from selling to independents—in just the same way that a company like Häagen Dazs or Carnation benefits by being able to sell its ice cream through retail outlets it does not own. The benefit is wider marketability of the product. An oil company benefits by selling to independent stations even if they are in direct competition with stations it owns, because it is better that *it* supply the competing stations than that some other oil company do so—if that happened, it would still have the same competition, but it would sell less gasoline. In the absence of price controls, even the physical scarcity of oil would not have stopped the oil companies from selling to the independents. They would have been glad to sell whenever an independent was in a position to pay a price higher than their own stations could afford.

The Conspiracy Theory of Shortages

I cannot help noting that this whole argument about the oil companies being out to eliminate the independents (or even just being out to build the Alaskan pipeline), and allegedly staging a nationwide, worldwide crisis to do it, introduces a strange element into the discussion. That is the element of alleged secret plots, dark conspiracies, evil forces, and all the rest of that syndrome.

Strange to say, this kind of argument is much more prevalent than one might imagine. It is present in implicit form whenever anyone asserts that a shortage, whether of oil or anything else, is "contrived." This view of things is not only ignorant of all the consequences of price controls, but it implies the existence of a secret conspiracy. It assumes that price controls themselves create no problems, but that the problems are created by the evil of private firms who combine together secretly and arbitrarily to produce the consequences we have seen can result only from price controls.

In view of all that we have proved about shortages in general and about the oil shortage in particular, I believe I am justified when I say that these arguments really deserve no greater intellectual respectability than the fear some unfortunate people have of Martians or the evil eye. Certainly, they should not be taken seriously by the

media or by public officials, as, unfortunately, they have been. It is the intellectual and moral responsibility of the media and the public officials to stop engaging in slander based on ignorance and fear, and to acquire the enlightenment provided by economic science.

Rebuttal of the Charge That Private Firms “Control” Prices

A rather vicious argument has been advanced as a justification for the imposition of price controls. This is the argument that private firms already “control” prices, only they “control” them in their own selfish interest. Instead, it is urged, the government should control prices, for it will do so in the “public interest.”

This argument was repeatedly presented in television commercials during the campaign for the 1976 Democratic presidential nomination by one of the leading contenders, Representative Morris Udall. Representative Udall repeatedly asserted that he believed that instead of the price of oil being “controlled” by the oil companies, in their selfish interest, it should be controlled by the president (i.e., Morris Udall), in the public interest.

The reason that Representative Udall and others believe that private firms “control” prices is that they can observe the producers of manufactured or processed goods, and also retailers and many wholesalers, engaged in the *setting* of prices. For example, these businessmen (or their employees, acting under their instructions) can be observed sending out price catalogs and price lists, and also posting prices on signs and writing them on tags. To set prices in this way is, according to Representative Udall and others, to “control” prices. The essential characteristic of a controlled price, on this view, is that someone sets it. It is considered secondary and inconsequential *who* sets it—whether a private businessman or a government official. Indeed, since prices do not create themselves, it is difficult to understand how, on this view, any price can avoid being described as “controlled.”

The distinction seems to be that a price is not considered controlled if it is formed in markets so broad—like the organized exchanges for common stocks and commodity futures—that it is difficult to trace from precisely whom any given price quotation emanates; such price quotations have the appearance of being formed independently of any definite individual. If, on the other hand, price quotations emanate regularly from the same, easily identifiable source—such as a steel mill’s published price at which it stands ready to ship steel, or a candy store’s sign announcing the price at which it stands ready to sell candy bars—the price is declared to be “controlled.” (Often, the word “administered” is used as a synonym for “controlled.”) The supporters of this idea rarely mention the fact that they believe candy stores and

barbershops and the like are engaged in “price control”—they confine their attacks to large firms, like steel companies and oil companies, where they can count on envy and the existing hostility to big business—but that is the logic of their position.

The viciousness of this doctrine is that it evades and seeks to obliterate the fundamental and radical distinction between private action and government action.²⁴ Private citizens, and this, of course, includes private corporations, have no authority to resort to physical force against other people. If they do, they are in violation of the law and will be punished. Private action, therefore, is essentially voluntary in character—that is, it can only occur by peaceful means, with the mutual consent of all involved. Government action is totally different. The government has legal authority to resort to physical force—e.g. to arrest, fine, imprison, and even execute people. All government actions rest on this authority. There is no such thing as a law (or a ruling, edict, or decree) that is not backed by the threat of physical force to assure compliance.

Let us see what difference these facts make to whether prices are set by private firms or by the government. When prices are set by private firms, they are set with regard to the mutual self-interest of the buyer and seller, including the need to take into account the threat of competition or potential competition. Thus, a seller must ask prices that are not only high enough to enable him to stay in business and make the best possible profit he can, but, simultaneously, that are low enough to enable his customers to afford his goods and too low for other sellers or potential sellers to try to take away his market.

When the government sets prices, its prices are backed by the threat of physical force, and are necessarily against the mutual self-interests of buyers and sellers. The government invariably tries to sacrifice either the seller to the buyer (by imposing prices that are too low), or the buyer to the seller (by imposing prices that are too high). In the one case, it succeeds in destroying the sellers, leaving the buyers without suppliers. In the other case, it succeeds in destroying the buyers, leaving the sellers without customers (or the workers without employers).

This is the difference that is made by whether prices are set by private firms or by the government. This is the difference that Congressman Udall’s usage of the term “price control” evades and seeks to obliterate.

Private firms do not and cannot control prices because they have no power to resort to physical force. Only the government can control prices—i.e., only the government can use force to set prices in violation of the mutual self-interests of buyers and sellers. Price control means not the setting of prices, but the setting of prices *by the government*.²⁵

PART B

FURTHER EFFECTS OF PRICE CONTROLS AND SHORTAGES

1. Consumer Impotence and Hatred Between Buyers and Sellers

Once price controls result in shortages, their destructive effects are greatly increased. The combination of price controls and shortages not only deprives the consumer of the power to make it profitable for sellers to supply the goods he wants, but of all economic power of any kind over the seller. Instead of being a valued customer, whose patronage or lack of patronage makes a difference to the seller's profit or loss, the buyer is reduced to the status of absolute insignificance, totally at the seller's mercy. His position is much worse, in fact, than if he were dealing with a protected legal monopolist.

Consider. If a shortage exists, and a buyer is dissatisfied with his supplier, he dare not leave him, because he has nowhere else to go. In a shortage, even if there are many other suppliers of the same good, each of them has his own waiting line or waiting list, and, as a result, the dissatisfied customer of any one supplier cannot count on actually being supplied by any other supplier. The other suppliers, therefore, do not represent a real alternative for him in a shortage. Consequently, no matter how many sellers of a good there may be, price controls and shortages place each of them in the position of being the only one. In addition, just as in the case of a protected legal monopolist, these sellers are immune from potential competition. (The threat of potential competition, in a free market, would keep in check the occasional sellers who were in the position of being sole suppliers.) Potential competition is ruled out because the industry is forced to operate at a rate of return that is not competitive, and perhaps even at an outright loss. As a result, no outside firm would want to enter such an industry.²⁶

The situation for the customer is worse than if he were dealing with a protected legal monopolist, because under price controls and shortages, the seller who surpasses a customer's limits of tolerance and succeeds in driving him away *does not lose anything by doing so*. This is because for each customer who is driven away, there is a multitude of others eager to take his place. The seller simply sells to someone else who otherwise would not have been able to buy or not buy as much as he desired. This goes beyond the conditions faced by a protected legal monopolist, because such a monopolist does not have a reserve of unsupplied potential customers willing to buy on just as good terms as his present customers. If

such a monopolist drives away his present customers, he can find new ones only at lower prices. A protected legal monopolist who has any sense, therefore, will not do this. He will value his customers, because he knows that he cannot afford to lose them without harming himself. But under price controls and shortages, the seller is free to regard his customers as absolutely valueless—as being instantaneously replaceable by others drawn from waiting lines or waiting lists without any loss to himself.

By the nature of the case, shortages lead sellers to regard customers not only as valueless, but as a positive nuisance—as a source of trouble and expense, not a source of livelihood. This occurs because, in fact, under a system of shortages and waiting lines, that is just what customers become. Under such a system, when a seller renders a customer some service or goes to some expense on his behalf, he is no longer doing it for the sake of gaining or keeping the customer's business and thereby earning his own livelihood, because having the customer's business no longer depends on performing the service or incurring the expense. The seller can have the customer anyway, or, if not that customer, then any one of ten or a hundred or a thousand other customers. If the seller is to continue to provide the service or incur the expense for the sake of the customer, he can only do so out of a sense of altruistic duty, not out of the sense that in serving the customer he serves himself.

Thus, price controls and the shortages they create take the profit out of serving the customer and the loss out of not serving him. They break the harmonious union of the self-interest of buyer and seller that prevails in a free market and replace it with an altruistic relationship between the two. In this relationship, the customer is reduced to impotent pleading for the customary service and customary quality that the seller no longer has any economic motive to supply. Indeed, all of the seller's motives, both economic and noneconomic, now work in the direction of reducing the quality of his product and the service associated with it.

The seller's economic motive lies with reducing quality and service because by doing so he reduces his costs and perhaps his own labor, and he does not have to fear any reduction in his revenues. For the same reason, employees feel free to work less hard in serving customers. Their poor performance no longer threatens their employer's revenue, and so he is no longer motivated to make them produce high quality products and to treat customers properly. (Thus, even under price controls, there is a tendency for customers to get what they pay for. To the extent that they pay prices below the potential free-market prices, they tend to receive products that are below the level of the products they would have received in a free market.)

The fact that price controls inflict actual harm on the sellers, and the fact that this harm is inflicted for the avowed purpose of benefitting the buyers, introduces a noneconomic element into the attitude of many sellers. They see themselves as being sacrificed for the benefit of their customers, and they may actually come to hate their customers as a result of it. In some cases it is possible that they may derive actual pleasure from the reduction in quality and service that they impose on their customers.

Price controls and shortages, in fact, launch a spiral of mutually reinforcing hatreds between buyer and seller. The buyer arbitrarily demands the quality and service he is accustomed to, even though he is not paying the necessary price any longer. The seller has no economic reason to comply with these demands, but, on the contrary, has both economic and psychological reasons not to. The buyer then views the seller as an omnipotent tyrant whom he must beg for favors or threaten with reprisals in order to obtain what he wants. The seller views the buyer as a hysterical petty chiseler seeking values without payment. To the degree that the accustomed quality and service are not forthcoming, the buyers become more shrill and insistent in their demands, and the sellers become correspondingly more resistant.

This principle—of deterioration of quality and service accompanied by mutual hatred between buyer and seller—was illustrated to some extent in the gasoline shortage of early 1974. Suddenly, service station attendants who had always cleaned windshields and eagerly volunteered to check under the hood ceased to do so. Whereas before they had always been courteous and polite, seeking to encourage as much repeat business as possible, they now became surly and rude. The customer, who had always been king at the gas station, as everywhere else, suddenly became a useless pest waiting in line to have his tank filled and causing unnecessary labor to gas station attendants. The breakdown of the normal harmony of interests between buyer and seller, and its replacement with open hostility, was strikingly illustrated in a *New York Times*’ “Quotation of the Day.” (I quote first the statement quoted by *The Times* and then its description of the person and circumstances surrounding the quotation. I omit the individual’s name, in order to spare him possible embarrassment.) “‘If he’s that stupid, he waits in line an hour and doesn’t know the rules, I let him get to the pump—and then I break his heart.’— . . . a service station attendant in Elizabeth, N.J., where gasoline rationing rules went into effect yesterday.”²⁷ (For the benefit of readers who may be unfamiliar with the circumstances, what the attendant let unsuspecting motorists wait in line an hour to find out was that they were there on the wrong day: their license plates ended with an odd

number when they should have ended with an even number, or vice versa.)

The shortage of gasoline did not last long enough to make hatred between motorists and service station attendants become a regular feature of life. With the ending of the oil shortage in the spring of 1974, normal relations were restored, and the conditions of early 1974 were soon largely forgotten. A more enduring and, therefore, probably more significant example is afforded by the relations between landlords and tenants in places like New York City, which has had almost continuous rent control since early in World War II. In New York City mutual hatred between landlords and tenants is commonplace. It has become the norm. Nothing is more frequent than complaints about things landlords do not do, unless it is complaints about things they are trying not to do. For example, depending on the particular circumstances, landlords do not provide, or are trying to avoid providing, such services as doormen, painting, repairs, and even heat. Tenants regard all of these things as theirs by right, and hate the landlords for not supplying them or trying not to supply them. Landlords, on the other hand, often regard the tenants as people who want to live without paying the proper rent. And, in many cases, while they watch the real value of their investments shrink to zero, they observe tenants able to afford expensive automobiles and adopt a style of life that is above their own—made possible by the low, controlled rents they pay. In such circumstances, there are landlords who derive positive enjoyment from such things as providing no heat, as well as save money by it.

Of course, it should be realized that there are also many cases—and undoubtedly a far greater number—in which the controls simply make it impossible for a landlord to provide many things, even if he wants to for the sake of keeping up his building, such as a new boiler or wiring system or any major repair or improvement. The controls often make these things impossible by leaving the landlord with too little capital to make the necessary investments. In the long run, controls must produce a progressive elimination of services even if landlords have the best will in the world.

How Repeal of Rent Controls Would Restore Harmony Between Landlords and Tenants

The hatred between landlords and tenants would disappear in a rental market that was free of controls. Such a market would restore economic power to the tenants: it would give tenants the power to make landlords serve them out of self-interest.

Consider how a free market would bring this about.

The first effect of the establishment of a free rental market would be a jump in the previously controlled

rents. This jump in rents would eliminate the shortage of rental housing. Immediately, even before any increase in the supply of rental housing could occur, the rise in rents would level the quantity of living space demanded down to equality with the limited supply that exists. In fact, the quantity of living space demanded would be reduced to a point somewhat below the supply that exists: landlords would have some vacancies on their hands at free-market rents. Precisely these vacancies are what would restore to tenants their economic power over landlords. At free-market rents, each tenant would be able to choose from a large number of apartments available in his price range. If he did not like the service his present landlord gave him, he would simply move when his lease expired. He would not be in the position of having to regard his present apartment as the only one in the world, and feel obliged to stay no matter how bad conditions in it became. By the same token, his landlord would no longer be able to count on easily replacing him. At free-market rents, his landlord would not have a waiting list of potential tenants, but vacancies on his hands. If he were to act in such a way as to make too many tenants move, he would either be unable to replace those tenants or he would have to reduce his rents below the general market in order to attract replacements. In this way, a landlord who did not satisfy his tenants would suffer financial loss. The landlord's self-interest would once again make him want to gain and keep tenants. Landlords would once again begin to compete with each other in terms of improved quality and service. They would have to, because they would need tenants once again, while tenants would no longer need any particular one of them.

2. The Impetus to Higher Costs

A major consequence of price controls and shortages is that they increase costs by means of creating various inefficiencies.

For example, in those cases in which goods come in a variety of models and price ranges, such as television sets, cars, lawn mowers—most goods—they create an incentive for producers to eliminate the more economical models while cutting corners in the production of the more expensive models. The reason this occurs is that, on the one hand, the buyers are able and willing to pay the higher prices of the more expensive models rather than do without the good altogether, and, on the other hand, corner cutting can generally be carried out more easily and with less serious results on the upper end of a product line than on the lower end. The process is actually a disguised way of raising prices and restoring profits. But it is a very uneconomic way of doing so, because, as a result of it, many buyers end up having to

pay more for more expensive models that they don't really need or want than they would have had to pay in a free market for the models they really do want. For example, someone seeking a sixteen-inch black-and-white television set may end up having to buy a nineteen-inch color set, because that's all that's available. At the same time, the buyers who do want the better models find they are not as good any more.²⁸

This process is a corollary of the decline in quality and service discussed in the previous section. And as soon as a shortage becomes severe enough, quality and service are cut to the point that buyers are offered models that would never appear in a free market in any price range. What happens is that sellers are led to cut corners in order to make relatively small savings to themselves and which have a great impact on the buyers. For example, situations can exist in which it is advantageous to a seller to save a few cents in manufacturing costs that later imposes many dollars in repair costs on the buyer. The harm inflicted on the buyers does not cause the sellers any economic loss, because at the controlled price there is a surplus of buyers eager to buy even a very inferior product.

In the same way that price controls and shortages make it impossible for a consumer to select his model on the basis of cost, they also make it impossible for a businessman to select his *methods of production* on the basis of cost. For one or more of the factors of production he requires may simply be unobtainable, because a price control has created a shortage of it. Under price controls, businessmen must select those methods of production for which the means happen to be available, and not necessarily those which have the lowest costs. The inability to find the right factors of production, of course, also frequently results in a decline in the quality of products as well, and should be viewed as a further and major cause of declining quality. The very deterioration of quality and service is itself a powerful source of higher costs both to businessmen and consumers, as I have already indicated. If, for example, a machine is produced or serviced in an inferior way, then even if its price remains the same, it will cause higher costs of maintenance and repair and may have to be replaced sooner. The same obviously applies to many consumers' goods. If a television set lasts only half as long and has to be repaired twice as often, it is a lot more expensive to own, even though its price remains the same.

Shortages of supplies and the mere threat of shortages themselves directly raise the costs of production. The effect of a shortage of a factor of production is to delay production. This causes the capital invested in all the other, complementary factors of production that depend on it, to have to be invested for a longer period of time

than would otherwise be necessary. For example, a shortage of building-nails causes capital to be invested in half-finished houses and in piles of lumber for an unnecessary period of time. Since interest must be paid on capital for the full time it is invested, the effect of all such delays is to raise the interest cost of production. Similarly, the mere anticipation of shortages of supplies leads businessmen to hoard supplies of all types. This requires that production be carried on with a larger capital investment—in the additional stocks of supplies and in facilities for storing them. And this, of course, in turn, means extra interest costs and extra costs on account of the storage facilities. Finally, there is the loss of the valuable time of executives in searching for sources of supply and in performing all the paperwork required to comply with the government's price controls and any associated regulations, such as rationing.

It should be noted that shortages and the threat of shortages also directly raise costs to consumers. Consumers too suffer effects analogous to wasted investment and the need for more investment. For example, consumers who could not obtain gasoline could not use their cars or enjoy their country homes until such time as they could obtain gasoline. To that extent, the money they had spent for these complementary consumers' goods represented a kind of wasted investment. In addition, of course, consumers too are led to hoard supplies and thus to tie up larger sums of money in stocks of goods and, quite possibly, incur additional costs on account of acquiring extra storage facilities—for example, extra home freezers, if there should be the threat of a food shortage. Finally, one must mention the wasted man-hours spent in waiting lines during every shortage, which, while not a money cost, are nonetheless a real hardship and burden and can well be at the expense of actual working time.

To some extent, the rise in production costs that price controls and shortages bring about may come out of profits. But it certainly does not always do so—as, for example, when it is a case of concentrating on the production of more expensive models that have correspondingly higher controlled prices. Moreover, it is possible for most or even all of the rise in costs not to come out of profits—at least, not out of nominal profits. For the government may very well follow a policy of allowing prices to rise insofar as the producers can prove a rise in costs. This was the case to a large extent in World War II. During World War II, most defense contracts were written on a cost-plus basis—that is, the government paid defense contractors their costs plus a percentage of their costs as profit. The same principle seems often to have been applied in setting the price controls on civilian goods. This procedure, it should be realized, is tantamount to the positive encouragement of extra costs,

because it makes the incurrence of extra costs the way to raise profits. It thereby totally perverts the profit motive from being the driving force of greater efficiency to being a driving force of greater inefficiency.

By their very nature, price controls pervert the operation of the profit motive. One must charge to their account not only all of the actual inefficiencies they create, but all of the potential improvements in efficiency they prevent. Price controls create a situation in which it is no longer necessary to reduce costs or improve quality in order to raise profits. In a free market, the price every firm receives is the very best it can obtain under the prevailing state of the market. A firm has the legal right to ask a higher price than this in a free market, but does not ask such a price because it would drive away too many customers: its customers would turn to competitors, and new competitors would probably appear; or, even if there were no close competitors, its customers would simply buy too much less of its type of product to make a further rise in price worthwhile.

Thus, in a free market, a firm must accept the fact that its price is limited by forces beyond its control. In order to increase its profits, it cannot simply raise its price—it must reduce its costs of production or improve the quality of its products to attract new buyers. That is final. There is simply no other choice. But under price controls, the price a firm receives is not something that is imposed upon it by an unyielding external reality, to which it has no choice but to adapt its own conduct. The price it receives can be changed in its favor—if only it can prevail upon the officials in charge of the price controls to relax them, or if it can find ways of evading them. Thus, the firm's focus necessarily switches. Instead of being focused on reducing costs and improving quality as the ways of increasing profits, it becomes focused on ways to have the price controls relaxed or to evade them. This alone represents a radical change in the way a firm directs its talents and energies.

Furthermore, as we have seen, firms lose the incentive to reduce costs or improve quality. Price controls and the shortages they create place *these things* beyond a firm's power. Even if it wanted to, a firm has no power to reduce its costs or improve its quality when shortages prevent it from obtaining the appropriate means of producing its products or cause the quality of those means to deteriorate. But, of course, even if it had the power, there is simply no reason under price controls and shortages for a firm to reduce its costs or improve the quality of its products. There is no reason to improve the quality of its products, because its customers will snap up goods of lower quality than it now offers. It has no reason to reduce its costs (except at the expense of quality) in an environment in which customers are eager to pay prices that

would cover substantially higher costs and in which, besides, it has little or no prospect of profiting from any improvements in efficiency it might achieve.

This last is the situation of every price-controlled firm in a period of inflation, insofar as its suppliers are still free to raise their prices or to impose higher costs by virtue of declines in the quality of their products or services. Such phenomena will raise the costs and destroy the profitability of a firm that must operate under price controls, no matter what it does to control its costs by means of becoming more efficient. To the extent that it succeeds in retarding the rise in its costs through greater efficiency, the price-control authorities will use that very fact to deny its need for a price increase. The only effect of achieving greater efficiency in such a situation is to postpone the day that one is permitted to obtain relief by raising one's prices. In other words, normal cost reductions, based on improvements in efficiency, simply cease to pay, even if they are still within the firm's power to make. The only cost reductions that pay under price controls are the ones that can be made effortlessly, namely, cost reductions at the expense of quality—the kind of cost reductions that would not pay in a free market.

In sum, price controls and shortages thoroughly pervert or destroy the operation of the profit motive. In place of profit incentives to improve quality and reduce costs, they make it possible to profit by means of reducing quality and allowing costs to rise. For they destroy the resistance of buyers to declining quality and to higher prices to cover higher costs. Indeed, they often necessitate declining quality and positively encourage higher costs insofar as they entail cost-plus pricing.

The Administrative Chaos of Price Controls

It should be realized that the willingness of the government to allow higher controlled prices on the basis of higher costs of production introduces a significant complication into the administration of price controls. The complication arises because different parts of the supply of the same good will have different costs of production. As a result, the government must set a *number* of controlled prices on the identical good, depending on the particular cost of production incurred to produce the particular batch of goods in question. This procedure is generally accompanied by further procedures, all of which help to make price controls an administrative nightmare.

What the government does is to allow producers to sell to distributors (or to further processors) at varying prices, corresponding to their varying costs. The distributors, however, are required to sell to the ultimate consumers at a *uniform* price, based on an average of the varying costs to them as a group. By itself this procedure would threaten some distributors with financial ruin while

offering other distributors the prospect of correspondingly higher profits. For all distributors must sell at the same price, while their costs may be significantly above or below the average on the basis of which that price is set. In order to deal with this problem, the government must assign to each distributor his "fair share" of low-cost and high-cost goods, or force the distributors to agree to some scheme of mutual compensation.

This sort of situation existed in the oil industry when it was under price controls. Oil produced from wells that had been in operation prior to the imposition of price controls in August of 1971, was classified as "old oil" and controlled at a price of \$5.25 a barrel. Oil produced from wells brought into production subsequent to that date was called "new oil" and was controlled at approximately twice that price. Those firms that were supplied mainly with "old" oil were forced to compensate the firms that had to rely mainly on "new" oil, or on imported oil, which, since early 1974, was not subject to controls at all and (prior to the Iranian revolution of 1979), sold for about \$14.50 a barrel. The compensation arrangement resulted from the fact that all the oil companies had to sell at essentially the same prices to consumers, and the consumer prices were based on an average of the price of old, new, and imported oil. Under this arrangement, some oil companies were forced to turn over hundreds of millions of dollars, called "entitlements," to other oil companies.

The entitlement system was not only administratively chaotic, but actually represented an expropriation of the wealth of American oil companies for the benefit of the Arabs. Under it, the profits that were made by refiners that bought "old" oil at \$5.25 a barrel were transferred largely to those refiners that bought Arab oil at \$14.50 a barrel. This meant that money that should have gone to purchase American oil was instead used to finance the purchase of Arab oil. It was literally a system for keeping money out of the hands of American producers and putting it into the hands of the Arabs.²⁹

3. Chaos in the Personal Distribution of Consumers' Goods

In the last chapter, we saw that, in a free market, consumers' goods in limited supply are distributed to the individual consumers in accordance with a combination of their relative wealth and income, on the one side, and the relative strength of their needs and desires for the goods, on the other.³⁰ Price controls and shortages totally disrupt this principle of distribution. What they substitute is not another principle, but merely the rule of the random, of the arbitrary and the accidental—the rule of chaos.

One should think back to the gasoline shortage and consider what determined the distribution of gasoline. It was a matter of luck and favoritism. Gasoline went to those who happened to be on the spot when deliveries were made to gas stations, or who had the time to waste waiting hours in line or following gasoline delivery trucks around. It went to those who happened to be friendly with service station owners or the employees of service stations. Both the wealth and the needs of the buyers were made irrelevant. The country's most productive businessmen were placed on an equal footing with welfare recipients: the value of their higher incomes was simply nullified. It was just a question of who arrived first or who had the right friends. By the same token, people whose very livelihood depended on gasoline were in no better position to obtain it than people wanting it for the most marginal purposes. Again, it was just a question of who got there first or who had the right friends.

Rent-controlled apartments are distributed in just the same way. If meat were placed under price control, it would not be long before it too was distributed in this way. The distribution of any good subjected to price controls becomes chaotic just as soon as the controls produce a shortage.

4. Chaos in the Geographical Distribution of Goods Among Local Markets

We already know that price controls prevent an area that has an urgent need for a product from obtaining it by bidding up its price in competition with other areas. When price controls are joined by shortages, a further major element of chaos is introduced. Under the combination of price controls and shortages, not only is the price of a good prevented from rising, but also, paradoxically, it is prevented from *falling*.

Where a shortage exists, an increase in the supply of a good, or a decrease in the demand for it, does not reduce the price; *it merely reduces the severity of the shortage*. Where a shortage exists, an additional supply merely makes it possible for someone to buy at the same—controlled—price who previously could not do so; likewise, a decrease in demand merely means a reduction in the number of those contending for the supply who must go away empty-handed. The price does not fall in such circumstances because it is already too low, as a result of price control.

The significance of the fact that prices can neither rise nor fall is that if price controls and shortages exist in various local markets, producers are in a position to sell a larger quantity in every such market without any reduction in the price in that market or, therefore, in the

profitability of sending supplies to it. All that they have to do is find an additional supply of the good to send. What this situation makes possible, in essence, is that producers can send their goods practically anywhere, in widely varying proportions, and it doesn't matter to them. If they send too little to some areas, the price controls in those areas prevent prices and profitability from rising and halting the drain. Meanwhile, in the areas into which they are sending too much, shortages prevent prices and profitability from falling and stemming the inflow. In a word, the geographical distribution of a good simply becomes random and chaotic, disconnected from the consumers' needs and purchasing power.

Consider the following case, based on the experience of the gasoline shortage. The price control on gasoline created a shortage in the whole northeastern region of the United States. Almost every state and locality in that region had its own individual shortage. In this context, it largely ceased to matter to the oil companies how their gasoline was distributed among the various areas in the region. Suppose, for example, that they sent a million gallons less a month to New Jersey and a million gallons more a month to Connecticut. It didn't matter to them. The price of gasoline in New Jersey and the profitability of sending it there could not rise even if New Jersey received hardly any gasoline at all. Price controls prevented it. At the same time, the price of gasoline in Connecticut and the profitability of sending it there could not fall—until the shortage in Connecticut was totally eliminated. Of course, just the reverse could have occurred. A million gallons less a month could have been sent to Connecticut, and a million gallons more a month could have been sent to New Jersey. Price control would have prevented any rise in the price and profitability of sending gasoline to Connecticut; and, so long as it existed, the shortage would have prevented any fall in the price and profitability of sending gasoline to New Jersey.

This indeterminacy introduced by price controls explains how some areas can suffer relatively mild shortages, and other areas very severe shortages, and how their positions can easily be reversed. The significance of this is that price controls not only create shortages, *but make it a random matter how the burden of those shortages is distributed*. In the gasoline shortage, for example, it would have been possible for the various areas to share the burden of the overall shortage in any proportions. All might have suffered more or less equally, or some particular areas might have borne almost the entire shortage, while others suffered almost none at all, or any intermediate situation might have existed. The actual chaos that did exist fully accords with this principle.

Precisely how the burdens are distributed is the result of accident. In the gasoline shortage, the main accidental

factor was that the Northeast happened to be the region most heavily dependent on imports, and so it bore the far greater part of the nationwide burden—given the fact that price controls prevented the people of the region from bidding up the price of gasoline and thus making the shipment of replacement supplies profitable. Within the Northeast, further accidental factors played a role, such as the very time of the year when the controls were imposed. To understand this last point, imagine that the controls are imposed in the summertime. In the summer, there is a large demand for gasoline in many resort areas. As a result, the wholesale price of gasoline in these areas is at a seasonal high in relation to the wholesale price in many city areas. It is high enough to cover such special summertime costs as may be entailed in having to bring in supplies from more distant refineries than is necessary at other seasons, when the local demand in the resort areas is smaller. The imposition of controls freezes this seasonal price relationship and carries it forward to the fall and winter, when there is a different pattern of demand, and when there should be a different set of gasoline price relationships to reflect it. Given the perpetuation of the summertime price relationships, what happens is that gasoline continues to be heavily supplied to the summer resort areas—perhaps to the point of pushing the price there somewhat below the level permitted by the controls. As a result, no shortage whatever exists in these resort areas. The entire shortage is concentrated in the cities. If the controls are imposed in the wintertime, instead of the summertime, then, of course, the reverse situation develops.

Further chaos in distribution can be caused by such things as small bureaucratic adjustments in the price controls. For example, it is quite possible that after the controls are imposed, the officials in charge may make some minor adjustments here and there, such as for the purpose of rectifying the kind of seasonal problems I have just described. In doing this, they can unleash major movements in supply which they may not be aware of causing. Imagine, for example, that they decide to permit, say, a penny a gallon rise in the price of gasoline in one particular major city. If this small rise makes this particular city a relatively more profitable market than other markets, the various distributors will want to sell more heavily in this city; and as long as a shortage exists in the city, they can do so without any reduction in the newly increased price and profit margin. The effect will be that this particular city will tend to be supplied very heavily, perhaps to the point of totally eliminating its local shortage, while supplies will simply disappear from other markets to the same extent.

Frankly, it is impossible to know all the different factors that might suddenly unleash major movements in

supply. The essential point is that under price controls and shortages, movements in supply have no effect on price and profitability until a local shortage is totally eliminated, at which point the local price and profitability will begin to fall and the further movement of supplies to that area will stop. Short of that point, massive movements of supply are possible in response to very small differences in profitability. Anything that can create such differences can cause such movement.

5. Chaos in the Distribution of Factors of Production Among Their Various Uses

The discussion of random geographical distribution applies equally to the distribution of factors of production in limited supply among their various uses. If a shortage exists of all the different products that a factor of production is used to produce, then there is a ready and waiting market for more of each such product. More of each such product can be sold without causing any reduction in its price or profitability, until the shortage of that particular product is totally eliminated. All that it is necessary for producers to do is find a way of getting more of any such product to the market.

In this situation, the allocation of a factor of production among its various uses becomes utterly chaotic. A factor of production can be withdrawn from the production of any of its products and added on to the production of any other of its products. The price and profitability of the product in reduced supply cannot rise to halt the decrease in supply. The price and profitability of the product in expanded supply cannot fall to stop the increase in supply, until its particular shortage has been totally eliminated.

Again, the oil shortage provides an excellent illustration of the principle. During the oil shortage there was a shortage of all the different oil products: gasoline, heating oil, jet fuel, propane, kerosene, etc. In these circumstances, it essentially ceased to matter to the oil refineries what they produced. If they took a million barrels of crude oil away from the production of gasoline and added it on to the production of heating oil, they could sell the additional heating oil with absolutely no reduction in its price or profitability, because of the shortage of heating oil. And if they did the reverse—if they took a million barrels of crude oil away from the production of heating oil and added it on to the production of gasoline—they could sell the additional gasoline with absolutely no reduction in its price or profitability, because of the shortage of gasoline. Of course, the price and profitability of the product being cut back could not rise—its price was controlled.

The result was that the production of the various oil

products was made random and chaotic. Practically any combination of products was possible. The only limits were those set by the possible total elimination of particular shortages. For example, gasoline production might have been expanded at the expense of heating oil production up to the point where the gasoline shortage came to an end and any further increase in the supply of gasoline would have forced a reduction in its price. At that point, the whole burden of the combined shortage of gasoline and heating oil would have been borne by heating oil. Or, of course, the reverse could have occurred. Heating oil production might have been expanded at the expense of gasoline production up to the point of eliminating the shortage of heating oil and throwing the whole burden of the combined shortage on gasoline production.

Either of these extremes or any intermediate situation was possible, and not just with regard to gasoline and heating oil, of course, but with regard to all oil products. Any of them might have been produced up to the point of no shortage, or any of them might have suffered a drastic reduction in production. Moreover, the position of the various products could suddenly have been reversed—with the relatively abundant ones suddenly becoming short, and the short ones suddenly becoming relatively abundant. Furthermore, if we add in the existence of geographical chaos, the situation could have been different in different parts of the country at the same time—for example, a severe shortage of gasoline and little or no shortage of heating oil in New Jersey and just the opposite in Connecticut.

The chaos that existed during the oil shortage fully accords with this description. And the same kind of random, accidental factors determined what actually did occur as in the case of geographical chaos. For example, the time of the year when the controls happened to be imposed played an important role in determining to what extent the overall oil shortage fell on heating oil or on gasoline. Controls imposed in the summertime tend to cause relatively abundant supplies of gasoline and a severe shortage of heating oil. This is because they impose the freeze at a time when the price of gasoline is high in relation to the price of heating oil, with the result that it is profitable to go on producing gasoline and not profitable to step up the production of heating oil even after the summer ends.

Conversely, controls imposed in the wintertime tend to cause a relatively abundant production of heating oil and a severe shortage of gasoline. Since our controls were originally imposed in August of 1971, it is not surprising that the first major petroleum product to develop a shortage was heating oil, which occurred in the late winter and early spring of 1973, months before the Arab embargo. (Subsequently, the government took spe-

cial steps to assure the supply of heating oil, and thereafter the burden of the oil shortage fell more heavily on gasoline and the other petroleum products.)

As in the case of geographical chaos, bureaucratic adjustments in the controls can cause sudden major shifts in supply among the various products of a factor of production. By making the production of any one particular product of a factor of production somewhat more profitable than the others, for example, the officials administering the controls can bring about a sudden expansion in its production up to the point of totally eliminating its particular shortage, while, of course, correspondingly worsening the shortages of other products of the factor in an unpredictable way. And if they suddenly reduce the profitability of a particular item, they can make the supply of it disappear and other items show up in its place, again, in an unpredictable way.

Anything that produces even slight changes in the relative profitability of the various products of a factor of production, whether a bureaucratic change in the price-control regulations, or anything else, can produce major changes in supply when shortages exist. As just one example, imagine that the uncontrolled price of some of the chemical additives used to make gasoline changed. If the prices of these chemicals rose, the profitability of gasoline might suddenly be reduced below that of other oil products. Since the price of gasoline could not rise as its supply was cut back, while the price of other oil products would not fall as their supply was increased, it would now pay to shift as much crude oil as possible away from gasoline production to the production of all other oil products. Conversely, if the price of the chemical additives fell instead of rose, then gasoline production would suddenly become more profitable, and a massive increase in gasoline production would probably occur at the expense of the production of all other oil products.

A principle that emerges from this discussion is that *price controls and shortages create tremendous instability in supply*. The supply of everything subjected to controls is subject to sudden, massive, and unpredictable shortages.

Hoarding

The chaos in supply caused by controls has a further important consequence, one that I have already noted in other connections, but which deserves some additional elaboration and stress here. This is the fact that shortages and the fear of shortages cause hoarding. If a person cannot count on being able to buy something when he wants it, because, overnight, it may disappear from the market, then he had better try to buy it when he can, so that he will have it available when he needs it. The effect

of this is that price controls and shortages artificially expand the demand for everything even more. Price controls not only expand the quantity of goods demanded by virtue of artificially holding down prices, but also by virtue of creating shortages and then the need to hoard, to cope with the shortages. The demand price controls create for the purpose of hoarding is a demand that does not exist even potentially in a free market—i.e., it is not even a submarginal demand—because it would serve no purpose whatever in a free market. But under price controls and shortages, hoarding becomes a matter of survival and greatly adds to demand.

The effect of this is that the irrationality of price controls goes beyond even what I have previously described. In the second part of the last chapter, I explained how price controls prevent the most vital and urgent employments of a factor of production from outbidding its most marginal employments. I explained, for example, how they prevented truckers delivering food supplies from outbidding housewives wanting gasoline for marginal shopping trips; how they prevented the operators of oil rigs needing oil products from outbidding homeowners seeking oil to heat their garages. Actually, the situation is even worse. Under price controls, the most vital and urgent employments of a factor of production are prevented from outbidding not only its most marginal employments, but, from the standpoint of a free economy, employments that could not even qualify as submarginal; that is, employments for hoarding purposes.

Under price controls and shortages it is entirely possible for people to be unable to get to work, to be without food, or even to freeze to death, not only because they are prohibited from outbidding the marginal employments of the oil, or whatever factor of production it may be, but because products are being hoarded by other people in fear of this very kind of possibility happening to them. The consequence is that price controls and shortages not only sacrifice men's well-being and very lives to the unearned, fleeting gains of other men, but, very largely, to a hoarding demand created by price controls themselves. In effect, men are sacrificed to the controls themselves.

6. Shortages and the Spillover of Demand

The effect of a shortage of any particular commodity is to cause the unsatisfied demand for that commodity to spill over and add to the demand for other commodities.

We have already had a glimpse of this principle earlier in this chapter, in our discussion of people ending up having to buy more expensive models of goods as the result of the unavailability of less expensive models. For

example, as we saw, the man who wants a sixteen-inch black-and-white television set may end up having to buy a nineteen-inch color set, because there is a shortage of the sixteen-inch sets and he cannot obtain one; so he settles for this substitute.

This principle applies not only to close mutual substitutes, such as different models of the same good, but also to goods which are totally dissimilar in their nature and function. For example, if our prospective buyer of a television set cannot find any model television set that satisfies him, he will eventually decide to buy some other kind of good. He may decide to buy a suit or to apply the sum he wanted to spend for a television set to the purchase of a better car or to any one of thousands of things or combinations of things. In this way, the money that price controls prevent from being spent in one channel is diverted to another channel.

This diversion of demand, it should be realized, takes place almost immediately. For example, even if our prospective television set buyer decides to add the price of the set to his savings, in the hope of being able to find the set later on, still, the demand for other things will rise almost immediately. This is because he will almost certainly deposit his savings in a bank, which will lend them out. As a result, a borrower will be put in the position of being able to buy something with the money our man had wanted to use for a television set.

The effect of this diversion or spillover of demand depends on whether or not price controls apply to the second-choice goods that people turn to. If these goods too are controlled, then the effect tends to be a worsening of the shortages of these goods. I will not elaborate on this consequence, however, until we begin our discussion of universal price controls, in the next part of this chapter. If price controls do not apply to the second-choice goods, then the effect of the spillover of demand is simply to drive the prices of uncontrolled goods still higher and to make the profitability of their production in comparison to that of the controlled goods still greater.

This principle concerning the effects of the spillover of demand in a partially price-controlled economy has a number of important implications.

Why Partial Price Controls Are Contrary to Purpose

First, the principle shows that "selective" or partial price controls, that is, price controls imposed merely on certain goods only, are contrary to any rational purpose the government might have in imposing them.³¹ The government imposes controls on the goods which it believes are the most vital. It imposes the controls because it believes they will enable people to obtain these goods who otherwise could not have obtained them

because of too high a price. The government leaves uncontrolled those goods whose production it considers to be relatively unimportant. The effect of this policy, however, is to destroy the production of the very goods the government regards as vital, while encouraging the production of the goods it considers unimportant. This occurs because the price controls restrict or altogether destroy the profitability of producing the controlled goods. At the same time, the shortages the price controls create cause demand to spill over into the markets for the uncontrolled goods and thereby make their production still more profitable.

For example, the government might control the price of milk on the grounds that it is a vital necessity, and leave uncontrolled the price of ice cream and soft drinks on the grounds that they are trivial “luxuries,” not worthy of its attention. The effect of this policy is to reduce the profitability of milk production in comparison with these and all other uncontrolled goods. As a result, it brings about a fall in the production of milk; this, together with the increase in the quantity demanded of milk resulting from its too low price, creates a shortage of milk. The effect of the shortage of milk is to cause the unsatisfied demand for milk to spill over into the markets for uncontrolled goods, including, of course, ice cream and soft drinks, whose relative profitability is then further enhanced.³² The effect of the government’s action, therefore, is to destroy the production of milk, which it regards as necessary and vital and wants people to have, and to promote the production of such goods as ice cream and soft drinks, which it considers unimportant.

Clearly, it would be less illogical if the government imposed controls on the things it considered unimportant and whose production it did not mind seeing destroyed, and left free the production of goods it considered vital. Nevertheless, governments do not do this, and again and again—in the early stages of a war, for example—they impose controls that undermine the production of necessities, while the so-called ash-tray industries and the night clubs and the cabarets flourish. For temporarily at least, these lines of business are left uncontrolled, on the grounds of being unimportant, and are therefore able to benefit from the spillover of demand caused by the shortages of necessities.

How Price Controls Actually Raise Prices

A second implication of the principle that shortages cause a spillover of demand and a rise in the prices of uncontrolled goods is that selective or partial controls cannot hold down the general price level. The expectation that they can is based on the erroneous belief that the problem of inflation consists in the rise of this or that group of prices and can be solved by prohibiting a

particular group of prices from rising. The fact is that such controls hold down the prices of some goods only by making the prices of other goods rise all the more.

Indeed, the effect of partial price controls is actually to *raise* the general price level. Partial controls have this effect, because while they leave aggregate demand and spending unchanged, they reduce the efficiency of production and, therefore, the aggregate amount of production and thus supply. We have seen that they can destroy vital industries, such as the electric power industry and the oil industry, on which the production of all other industries depends. In the course of destroying an industry, they reduce the quality of its products and the service associated with them, thereby raising maintenance and replacement costs for the buyers of the products. We saw also that controls cause resort to unnecessarily expensive models and methods of production, and lead to a system of cost-plus pricing. And we have seen that they create utter chaos in the geographical distribution of the products of a controlled industry and in the combination of the various products that such an industry produces; this disrupts all subsequent production that depends on these industries, and thus reduces aggregate supply. In all these ways, therefore, partial price controls actually raise the general price level.

The Absurdity of the Claim That Price Controls “Save Money”

A third, closely related implication is that the supporters of price controls are badly mistaken in claiming that any particular price control “saves people money,” and in arguing that the repeal of any given control will “cost” people this or that amount of money. This may be true in the short run for some individuals, who are lucky enough to obtain the goods they desire at below-market prices. But it is never true in the aggregate. In the aggregate, a control saves people money only in the sense of making them spend less for the controlled goods. At the same time, it makes them spend more for the uncontrolled goods. In the aggregate, they do not spend any less money. They do, however, receive fewer goods. Clearly, whatever saving or gain some buyers may have by virtue of controls is always at the expense of a greater loss to other buyers.

Indeed, in view of the fact that controls tend to destroy the controlled industries, the only kind of long-run “saving” they can achieve for anyone, including the people who might temporarily gain from them, is a rather bizarre one. It consists in preventing a person from spending the money he wants to spend for the goods he wants to buy. In this sense, the drivers who could not obtain gasoline at the controlled prices “saved money” on gasoline. Instead of having the gasoline they desperately wanted

and which they valued far above the controlled price, they had money left over to spend on other things which they wanted much less. Such savings are obviously absurd and contrary to purpose. They are comparable to making a person save money by not buying food or medicine, or anything he values more, so that he may have money for something he values less—if he is alive to spend it. Yet this is the only kind of “saving” that controls can achieve in the long run, and it is the only kind of saving they achieve right from the very beginning for whoever suffers from the shortages they create.

As will be shown in the next part of this chapter, total or universal controls—price controls on all goods—may be said to “save people money” in an even more bizarre way than partial controls. By virtue of creating a shortage of everything, and thus making money simply unspendable, universal controls enable people to save money in the sense of having it available for such purposes as papering their walls or lighting their fires with it. And as production declines under universal controls, and the volume of spending that can take place at the controlled prices accordingly drops further, the money that people “save” in this absurd way grows greater.

It follows from our discussion that in the aggregate the repeal of price controls would not cost people anything. If universal controls exist and are repealed, people would spend more money, but this greater spending would represent an exchange of otherwise useless paper for valuable goods, whose production would be greatly increased as a result of the repeal of the controls. If partial controls exist and are repealed, then the effect is a shift in the pattern of spending away from the previously uncontrolled goods to the newly uncontrolled goods. The prices of the former would tend to drop while the prices of the latter would tend to rise. But since the effect of the repeal is an increase in total production and supply, the general price level must tend to fall. For the same total demand with a larger total supply means a lower price level. The repeal of any partial control, therefore, must always tend to *reduce* the general price level by virtue of its effect of increasing production. It is only the repeal of a control, therefore, not the imposition of a control, that can truly be said to save people money.

Applications to Rent Controls

The principle that shortages cause the unsatisfied demand for controlled goods to spill over into the market for uncontrolled goods and to raise their prices has special application to rent controls as they have existed in places like New York City over most of the period in which they have been in force.

Such rent controls are partial price controls in an even more restricted sense than we have considered up to now.

They are partial controls not only in the sense that they apply only to specific goods, but also in the further sense that they apply only to part of the supply even of these goods. For example, in New York City all housing completed since January 1974 is totally exempt from rent controls. Prior to August 1971, all housing completed since February 1947 had been free of controls, and certain still earlier housing, considered “luxury housing,” had also been exempted. (All this previously uncontrolled housing is now subjected to controls in the form of government limitations on annual rent increases.) Perhaps even more important has been the fact that while rents have been controlled in New York City, they have generally been uncontrolled in the surrounding suburban counties and in most of the rest of the country. Nor have the prices of houses been controlled anywhere.

As a result of the fact that rent control has had only partial application, large numbers of people in New York City have been able to escape its effects. Those who could afford them have been able to find uncontrolled apartments or, in many cases, buy houses, co-ops, or condominiums in the city. Those who could not afford to live in New York City have been able to find places to live outside the city.

i. Internal Passports and Compulsory Assignment of Boarders

Before considering further the effects of the diversion of demand caused by partial rent controls, it will be well to project the consequences of controls applied to all of these alternatives. In other words, let us project the consequences of a fully price-controlled housing market on a regional and national scale. We will see that some of the potentially most disastrous effects of rent controls have been avoided because of the relatively limited scope of the controls.

If the entire housing market were controlled, housing would be artificially cheap in all of its forms and everywhere. The quantity demanded of all types of housing would therefore exceed the supply. This would be true all across the country. As a result, there would be a shortage of living space and no way around it. People would simply be unable to find space in New York City, and they would be unable to find it in the surrounding counties or anywhere else in the country. There would be people desperate for living space with absolutely no way to obtain it. They would need apartments and houses but with no better chance of finding them than they had of finding gasoline at the height of the gasoline shortage.

What might happen in such circumstances? The answer is two things worth thinking about: *The government would contemplate the restriction of the internal freedom of migration. And it would contemplate the assignment*

of boarders to private homes and apartments.

As to the first point, it would soon become obvious that in the circumstances of a pervasive housing shortage, the influx of additional people into any area would have the effect of making the local housing shortage worse. Each area would therefore become anxious to keep out as many new arrivals as possible on the grounds of their worsening the local housing shortage. Each area would try to set up barriers to in-migration and try to prevail upon the federal government to keep people where they were. As to the second point, the argument would be made that people cannot be left to sleep in the streets and that in the “housing emergency,” or whatever it might be called, it was necessary for those fortunate enough to have space, to share it with those not fortunate enough to have space.

This state of affairs has actually existed in many countries. For example, it was no accident, but precisely for reasons such as these, that the government of Soviet Russia deliberately restricted the number of inhabitants of its various cities and controlled the internal movement of the Russian population through a system of internal passports.³³ The Communist sympathizers and apologists who boasted about how inexpensive housing was in the Communist countries—extremely limited and wretched housing, it should be noted—did not realize that precisely this was what created a nationwide housing shortage in those countries. They did not realize that the low rents they were so proud of virtually necessitated restrictions on the internal movement of people—even apart from all other factors working in the same direction in the Communist countries. In addition, of course, as the result of the low rents and the consequent housing shortage, families could not take their privacy for granted in the Communist countries. Millions of families were forced to live in communal apartments. Often, two families had to share a single room, separated from each other only by a curtain—just as depicted in the movie *Ninotchka*.

Fortunately, in the areas of the United States where rent control has existed, such as New York City, people have been able to escape such disastrous effects, because the controls have been confined to a very limited part of the overall housing market. But, even so, the consequences have been severe.

ii. How Rent Controls Raise Rents

Let us pass over quickly the consequences of partial rent controls as they affect the part of the housing supply subjected to them, and then focus on the consequences as they affect the part of the housing supply that is left free of controls.

We know that controls create a shortage of the housing to which they apply because people scramble for apart-

ments at artificially low rents. We know that this fact, coupled with the lack of capital on the part of landlords that results from restricted profits, causes the quality of such housing to decline, in the process unleashing a spiral of mutually reinforcing hatreds between tenants and landlords. Ultimately, as the costs of operating buildings continue to rise, because of inflation, the effect of rent control is to cause widespread abandonments of buildings by their owners. Such abandonments have been going on for many years in New York City. As a result of rent control, there are growing areas in New York City—in the South Bronx, for example—that have been reduced to the status of a primitive village, with people living without electricity and having to fetch their water from public fire hydrants. (Such facts are reported every so often in *The New York Times*.)

As for the uncontrolled rental housing, we know that the shortage of rental housing that is under controls causes the unsatisfied demand for such housing to spill over and enlarge the demand for uncontrolled rental housing. This phenomenon and its consequences must be examined more closely.

The controls on rents bring space within the reach of people who otherwise could not have afforded it. That is their purpose and that is what they achieve. But to whatever extent the controls make it possible for some people to obtain space who otherwise could not have obtained it, they simultaneously *reduce* the space that is available for other people, who could have afforded to rent that space in a free market. These other people, of course, must then make their demand for space in a market that is less well supplied. The result is that rents on uncontrolled space in the area rise.

As far as the market is concerned, in addition to causing a diversion of the demand for housing, *partial rent controls are equivalent to a reduction in the supply of rental housing*. They take part of the rental housing stock off the market by giving it to people who could not afford the market rents. This leaves less of a supply of rental housing for the market and, consequently, increases rents on the diminished supply that is available for the market.

Perhaps the best and clearest way to understand these points is to think once again of the conditions of an auction. So imagine that an auctioneer is holding up two units of the same good. Imagine further that there are three bidders for these units. One bidder, imagine, is willing to bid a maximum of \$300 for one of these units, if necessary. Another bidder is willing to go as high as \$200, if necessary. The third bidder, assume, can afford to bid no more than \$100—that is his maximum limit in the bidding. In a free market, the price at which these two units will be sold will be above \$100 and below \$200.

The price will have to be above \$100 to eliminate the weakest bidder. It will have to be below \$200, in order to find buyers for both units. It will tend to be the same for both buyers because there is usually no way to discriminate between them. Let's assume the actual price turns out to be \$150: too high for the weakest bidder, yet low enough for both of the other bidders.

The weakest bidder has been excluded from this market. What must happen if we begin to feel sorry for him? Suppose people begin to feel so sorry for him that they get a law passed that orders the auctioneer to give him one of the units of the supply at a price he can afford—say, \$50. In that case, he gets his unit at \$50. But now, as a result of this, instead of the auctioneer having two units to auction off in the market, he has only one; the supply available for the market has fallen. And this one unit will now have to sell at a price somewhere above \$200 and below \$300—say, \$250. It has to be high enough now to eliminate *the middle bidder* instead of the weakest bidder. All that has happened is that one party has gotten part of the supply at an artificially low price and has caused the price on the remaining supply to go high enough to eliminate another party. The party eliminated could have afforded the market price if it were determined by the full available supply. But he cannot afford the market price *as determined by the artificially reduced supply*. Deprived of the supply that would have been available to him in a free market, his demand is diverted into a competition with the other remaining bidder, which competition, in the nature of the case, he must lose.

This auction example does not differ in any essential respect from the case of partial rent controls. Partial rent controls give part of the supply of housing to some people at below-market rents. To whatever extent these people could not have afforded as much space in a free market as they obtain under rent control, they leave that much less space available in the uncontrolled market. Consequently, rents in the uncontrolled market must rise that much higher—in order to level down the quantity demanded to equality with the reduced supply that is left for the market. For example, if the total rental housing supply in a city is one million rooms, and rent control results in giving half of those rooms to people who could not have afforded them at free-market rents, then rent control correspondingly deprives other people of those rooms who could have afforded them at free-market rents. In the process it makes the rents on the uncontrolled half-million rooms rise so high that that diminished number of rooms is all that people will be willing and able to rent in the uncontrolled segment of the market. In other words, rent control makes the open-market rents balance demand and supply at a supply of half a million rooms instead of a million rooms. People are

eliminated from the market who could have afforded market rents *as determined by the full supply of rental housing*. These people cannot afford market rents *as determined by the artificially reduced supply of rental housing that results from rent control*. Just as in the auction example, when deprived of the supply that would have been available to them in a free market, their unsatisfied demand is made to spill over into a competition with buyers who are able to outbid them for the reduced supply.

Obviously, the larger is the proportion of the housing stock under rent control, the higher must be the rents on the correspondingly diminished supply that remains for the open market. If this principle is understood, it should not be surprising that, for example, New York City, which has the largest proportion of rental housing under controls of any major city in the United States, also has, for that very reason, the highest rents in the nation on housing that is available for the open market.

The fact that partial rent controls act to raise rents on the uncontrolled part of the housing supply is reinforced by the fact that they increase the *costs* of providing rental housing. This occurs because the existence of controls on some housing today implies that the housing that is presently free of controls may later on be brought under controls. The threat of being brought under rent controls in the future makes it necessary for landlords of presently uncontrolled buildings to recover their investments more rapidly. For example, instead of looking forward to recovering their investments over a fifty-year period, say, the threat of rent control being imposed may make them want to recover their investments over a ten-year period, or even a five-year period, to be safe. This represents a great jump in the costs of providing new rental housing, and helps to explain why high rents on uncontrolled buildings do not result in corresponding new construction.

Insofar as rent control comes to be regarded as a regular institution, to be imposed at any future time the government may desire, the effect is to make today's tenants in uncontrolled buildings pay for the spoils of tomorrow's prospective beneficiaries of rent control. This artificial increase in the costs of new housing, it should be realized, is also one of the reasons why today's so-called luxury housing is often inferior in many respects to housing constructed in earlier decades. The reason is that it is not genuine luxury housing, but rather cheap housing that must be rented at luxury rates in order to offset the prospective losses that are expected to be caused by rent controls in the future.

Ironically, even if, however unlikely, rent controls were not expected to be extended to housing that is

currently free of them—indeed, if they were expected ultimately to be repealed—partial rent controls would still prevent the premium rents on uncontrolled housing from being eliminated by means of the construction of new housing. In a free market, it is true, rents tend to equal the costs of constructing and maintaining housing plus only as much profit as is required to yield the going rate of profit. Under partial rent controls, however, the rents on the uncontrolled portion of the market tend permanently to exceed this level, and exceed it the more, the larger is the proportion of the housing stock under controls. It is not only that the larger the portion of the housing stock under controls, the smaller is the supply remaining for the market, which is sufficient reason for the rents on the uncontrolled supply to be correspondingly high. But also the premium profits which such rents might be thought to offer for the construction of new housing are largely nullified by the consequences of the potential repeal of rent control no less than by the prospect of the extension of rent control. Consider. If the supply of uncontrolled housing were increased to the point that the rents on such housing were no higher than costs plus an allowance for the going rate of profit, the danger would exist that if rent controls were ever repealed, rents in the open market would then be driven below cost plus the going rate of profit. For the repeal of rent controls would throw back on the market all of the housing diverted from the market to tenants paying below-market rents. If open-market rents were already no more than equal to cost plus the going rate of profit, this increase in the supply available for the market would drive them below that point.

Thus, so long as they are in force, partial rent controls raise rents on uncontrolled housing, whether landlords expect them to be extended to the uncontrolled housing or to be removed from the housing to which they presently apply.

It follows from the preceding discussion that when partial rent controls are repealed, not only do rents in the open market fall, but the construction of new housing becomes much more profitable at any given level of open-market rents. For the repeal of the partial controls reduces the threat of new housing later on being subjected to controls, and thus extends the period of time over which investments in housing can be recovered. At the same time, the repeal eliminates any fear hanging over the market concerning the possible adverse effects of repeal on profitability. Thus, unless the decline in open market rents is quite drastic, the effect of the repeal of partial rent controls is not only lower open-market rents, but also a surge in the construction of new housing at those lower rents.

The repeal of partial rent controls and the decline in

open market rents that it brings is also accompanied by further substantial reductions in the costs of providing new rental housing, apart from that of a longer period of depreciation and correspondingly smaller annual depreciation charges. The decline in open-market rents on newly constructed buildings and thus in the market value of such properties is accompanied by a decline in the amount of taxes that such buildings must pay at the prevailing rates of property tax. Further declines in property tax on such buildings can occur by virtue of a fall in property tax *rates*, which is made possible by the rise in rents and property values, and thus property tax collections, in the case of the housing that had previously been controlled.

It is implicit in what I have just said, incidentally, that another of the destructive effects of rent control is a rise in property tax rates. This results from the destruction of the rent-controlled properties' ability to pay rising taxes in pace with inflation. Thus, the rates are increased on the properties left free of controls and on owner-occupied housing. Also, as the property tax declines as a source of revenue, local sales taxes and income taxes are imposed. They too, and all the unpleasantness that accompanies them, must be laid at least in part at the door of rent control.

iii. The Case for the Immediate Repeal of Rent Controls

The fact that partial rent controls increase the rents on uncontrolled housing is not recognized by the general public. The result is that the higher do partial controls drive rents, the more necessary do people believe rent controls to be; the more desperately do they cling to the existing controls and the more eager they are to urge the extension of the controls. They fear that the repeal of the existing controls would raise all rents to the level of the presently uncontrolled rents, and they believe that the uncontrolled rents are enormous because they are not controlled.

Our discussion shows that the best solution to the problems created by rent controls would be the *immediate* and total abolition of rent controls, accompanied by constitutional guarantees against their ever being reimposed. This would both immediately reduce rents in the open market and bring about the greatest and most rapid possible increase in the supply of rental housing.

Calling for the immediate abolition of rent control raises the question of what is to become of many of the people who presently live in rent-controlled apartments and who would have to move if rent control were all at once repealed. (In order to have some term to describe these people, let us refer to them as the "beneficiaries" of rent control—provided it is understood that they are

beneficiaries in a short-run sense only, and not genuine beneficiaries.)

Our previous discussion provides the answer to the question of what would happen to these people. In essence, the answer is that *they would simply have to change places with an equally large but generally unrecognized class of victims of rent control.*

Two facts about the immediate repeal of rent control must be kept in mind: not only would it raise rents to the beneficiaries of rent control, but also, as we have seen, it would simultaneously reduce rents in the open market, because the space presently occupied by the beneficiaries of rent control would be added to the supply in the open market.

What would happen in response to these changes in rents is two related sets of developments, the one affecting the beneficiaries of rent control, the other the victims. Let us consider the effects on the beneficiaries first.

In the face of a jump in their rents, some of the beneficiaries of rent control might have to share apartments or even single rooms with other people, in order to economize on rent. Others might have to move in with relatives. Still others might decide to move to remoter areas of the city, where rents were cheaper, or to leave the city altogether. It should be observed that none of the former beneficiaries of rent control would have to sleep in the street as the result of the rise in the rents they had to pay; they would simply have to occupy less space or live in less favorable locations. These points must be stressed, in view of the hysteria that is often evoked in projecting the allegedly dire fate of these people as the result of the repeal of rent control.³⁴

Now consider the fact that the apartments vacated by the former beneficiaries of rent control would not remain empty, but would practically all be occupied. For the rents on those apartments, though too costly for the rent-control beneficiaries, would represent a decline in the rents charged in the open market, and would thus come within the reach of new tenants. To use the same figures as in our auction example earlier in this discussion, assume that initially a beneficiary of rent control was paying a controlled rent of \$50, while rents in the open market were \$250. Now, with the repeal of rent control and the addition of the previously rent-controlled apartments to the supply available in the market, rents in the market fall from \$250 to \$150. A rent of \$150 is too expensive for the former rent-control beneficiaries. But it represents a reduction in rents in the open market and brings apartments within reach of people who could not afford them at the \$250-a-month rents caused by partial rent controls.

Let us focus on the new tenants who would occupy

the previously controlled apartments. Let us try to figure out who they would be and where they are now. These are people who could afford their own apartments in the city at \$150 a month, but not at \$250 a month. At \$250 a month, they find it necessary to share apartments (or single rooms), to live with relatives, or to live in remote areas of the city or out of town altogether. In other words, they find it necessary to do all of the things the beneficiaries of rent control might have to do if rent control were repealed. Perhaps some readers of this book may know some of these victims of rent control, though they probably have not thought of them in that light before. The victims are young people who must live with roommates, young couples who must live with in-laws, families that cannot afford to live in the city, and so on. These people represent the class of rent-control victims, though they are almost all unaware of that fact and see no connection between rent controls and their own plight. They are fully as numerous as the class of rent-control beneficiaries, and they are already suffering the same kind of hardships as the rent-control beneficiaries would suffer if rent control were repealed.

In fact, these victims of rent control are suffering vastly *more* hardship than the beneficiaries of rent control would suffer. For if rent control were repealed, the total supply of housing would quickly begin to expand and its quality would improve. In places like New York City, the supply would increase almost overnight, because the abandonment of buildings would cease, and many previously abandoned buildings would be restored. The hardship of the former beneficiaries of rent control would be temporary, because rental housing would once again become an expanding, progressing industry. As time went on, more and more of the former beneficiaries of rent control would be better off than they ever could have been under rent control. In the long run, everyone would be better off. The real answer to the question of what would happen to the present beneficiaries of rent control if rent control were repealed, therefore, is this: In the short run and at the very worst, they would suffer no more, and probably less, than what the victims of rent control have already been suffering for many years. In the long run, what would happen to them is simply more and better housing.

Furthermore, it should be stressed that in the long run, the very idea of someone being a beneficiary of rent control is a self-contradiction. The gains of the beneficiaries of rent control are made possible by the consumption of their landlords' capital. The tenant who is able to afford a better car, say, or an extra vacation, because of the artificially low rent he pays, is buying that car or vacation at the expense of part of a new apartment building somewhere, and ultimately he is buying it at the

expense of the upkeep of the very building in which he lives. The day comes when he wants to move and finds no decent place to move to, because he and millions of others like him have consumed the equivalent of all the new apartment buildings that should have been built. For they have consumed their landlords' capitals and destroyed the incentives for building. Finally, the day comes when they have consumed the equivalent of a new boiler or wiring system or plumbing system that their own building needs, and their landlord has neither the means nor the incentive to try to replace it. Then they live in cold, in darkness, and without running water. This is already the fate of tens of thousands of people in Harlem and in the South Bronx, as I have indicated. There is no reason why it could not happen to all rent-controlled housing in the country, given further inflation and more time. The only "gains" from rent control are the gains of consuming the capital invested in housing and then being left without housing. People do it because the housing belongs to the landlords, not to them. But in the long run, the loss is theirs, because they are the physical beneficiaries of the stock of housing. When they destroy the property of the landlords, they destroy the property that serves them.

How Repeal of Our Price Controls on Oil Reduced the Price Received by the Arabs

A further application of the principle that partial controls raise prices of goods that are free of controls concerns oil prices. It follows from this principle that our price controls on oil, which were in force from 1971 to 1981, raised the price received by the Arabs, and that their repeal immediately operated to reduce the price received by the Arabs. It follows further that a major effect of repeal was to undo the diversion of billions of dollars a year away from our oil industry to the Arab oil industry. The effect of this, in turn, was an expansion in the American oil industry and a still further drop in the world price of oil received by the Arabs. In other words, it follows that the dramatic decline in the world price of oil experienced in the 1980s can be directly traced to the repeal of price controls on oil in the United States.

In 1980, domestically produced crude oil in the United States was controlled at an average price of approximately \$10 per barrel. Imported crude oil was uncontrolled and sold at about \$34 per barrel, which was the price the Arabs received. Since the spring of 1974, the prices of the various oil products produced in the United States, such as gasoline, heating oil, and so forth, had been controlled on the basis of the weighted average of the uncontrolled price of imported oil and the controlled price of domestically produced oil. Since about half of our crude oil was imported and half was domestically

produced in 1980, the prices of oil products were set on the basis of an average cost of crude oil of approximately \$22 per barrel. Roughly speaking, the prices of oil products were set high enough to cover not only this weighted average cost of crude oil, but all the other costs of producing and distributing oil products and a more or less competitive rate of profit on the capital invested in refining and distribution. Such product prices did not differ radically from prices that would have existed had the free market price of crude oil been \$22 per barrel.

In order to see how this arrangement benefitted the Arabs and how its repeal brought back billions of dollars a year to our oil industry that had been diverted to their oil industry by price controls, all we have to do is think through the consequences of repealing our controls. Following repeal of our controls, the price of domestically produced oil immediately had to rise above \$10 a barrel. But the effect also had to be that the price of imported oil, and, therefore, the price received by the Arabs, fell below \$34 a barrel. To understand just why, imagine for the moment that the price of domestically produced oil simply rose all the way to \$34—the same price as the Arabs had been receiving. If that happened, the cost of producing oil products would have had to be based on an average price of \$34 a barrel of crude oil rather than on the previous average of \$22 a barrel. The prices of oil products would therefore have had to be raised correspondingly. But observe. At such higher prices, the quantity of oil products that could be sold would have been less, and, therefore, the quantity of crude oil that could be sold would also have been less. The only way to counteract this loss in sales would be if the prices of oil products did not rise by so much. The only way that that was possible was if the average price of crude oil did not rise by so much. But this implied that the price received by the Arabs actually had to *fall*. For in a free market our oil must sell for just as much as theirs; yet, we have just seen that their price of \$34 was too high for an *average* cost of crude oil—it would significantly have reduced the quantity of oil products and thus of crude oil that could be sold. Thus, our price could not have met theirs at \$34 a barrel. Our price and their price had to come together at some lower average figure.

Observe further. In order for the *same* quantity of crude oil to be sold in this country as was sold prior to the repeal of price controls, it would have been necessary for the Arabs' price to meet ours *at \$22 a barrel—the previous average price of crude oil*. For any higher price than \$22 required a rise in the price of oil products, which had to reduce the quantity of oil products that could be sold in this country and therefore the quantity of crude oil that could be sold in this country.

Indeed, one may raise the question of why the effect

of repeal was not actually to leave the price of oil products unchanged in the United States and simply reduce the price of Arab crude oil and raise the price of our crude oil to the previous average price of \$22. The reason these results did not occur was because one of the effects of decontrol was a reduction in *oil imports* into the United States. The price of \$34 for imported oil prevailed throughout most of the world. The price of imported oil could not fall to \$22 here while it was any higher elsewhere. What happened was that as the price of imported oil fell in this country, in the direction of \$22, less of it was sent here and more of it was sent to other markets. The result was that the United States reduced its import of oil and the price of imported oil settled at an amount above \$22. For a time, bolstered by cutbacks in their own production, the Arabs were able to maintain the world price at \$29 per barrel.

But subsequently, in the face of the pressure of growing supplies of crude oil produced in the United States, the world price of oil collapsed, despite all efforts of the Arab-led OPEC cartel to maintain it.

Thus, temporarily, the consequence of repeal was a rise in the average price of crude oil in the United States and a rise in the price of petroleum products in the United States. But the rise in price to American consumers was much less than the rise in price to American producers; much of the rise in price received by our oil companies was financed by a fall in the price received by the Arabs and other foreign suppliers. For example, when the price of crude oil temporarily settled at \$29 per barrel, the cost base of oil products for American consumers was increased by \$7 per barrel (from \$22 to \$29), while the price received by our oil companies was increased by \$19 per barrel (from \$10 to \$29). The rise in price received by our oil companies was financed in part by a \$5 drop in the price received by the Arabs and the other foreign suppliers (from \$34 to \$29).³⁵

Furthermore, as shown, this rise in domestic prices was merely a short-run effect, for oil production in the United States became substantially more profitable. Domestic oil production immediately began to expand, and as it did so, the world price of oil began to fall sharply. Temporarily it declined to as low as \$10. Currently, despite years of continued inflation, the price is approximately \$18 per barrel.³⁶

The preceding analysis can be presented in simpler, more dramatic terms in the light of the auction example I have used to explain why partial rent controls raise rents on the portion of the supply that remains uncontrolled.³⁷ Thus, one can conceive of the supply of oil consumed in the United States between 1971 and 1981 (the respective years in which the price control on crude oil was imposed

and finally repealed) as consisting essentially of two units: the half produced in the United States and the half produced outside, by OPEC and other foreign suppliers. The U.S. government compelled the half produced in the United States to be sold at a below-market price and thus more or less considerably to come within the reach of otherwise submarginal buyers, leaving correspondingly less of the supply of domestically produced crude oil available for the market. In effect, it compelled Exxon, Chevron, and Texaco to sell their unit of oil to the submarginal buyer for less than \$100, which left only one unit of supply available for the market, namely, the unit produced by Qadafi, the Ayatollah Khomeini, and Saddam Hussein, which unit could then be sold for a price of between \$200 and \$300. That was the essence of the situation. More precisely, in reducing the supply of American oil that a free market would have made available to American buyers, it forced American citizens into a competition for the remaining supply of oil in the market, a needless competition that many American citizens necessarily lost, and from which America's enemies in the Middle East greatly profited.

As I have indicated, such a policy might have been understandable if the U.S. government had been run by officials in the service of Libya, Iran, and Iraq. What its existence actually demonstrated, of course, was not that our officials were traitors in the service of foreign powers, but that they were men and women who, while intending to serve the American people, were intellectually unqualified to do so and, as a result, wreaked great harm upon them.

Given such incredible ignorance and destructiveness on the part of the U.S. government, it should not be surprising to learn of a further unnecessary tragedy inflicted on many American oil producers when the price control on domestically produced crude oil was finally repealed. Not content with simply repealing its price control and desisting from further acts of destruction against the oil industry, the U.S. Congress, acting on malice and greed, decided to confiscate a major part of the profits of American oil producers that resulted from their ability to receive a higher price of crude oil. In 1981, it enacted the so-called windfall-profits tax on crude oil as an accompaniment of the decontrol of oil prices. This was an act of malice in that its deliberate, overriding purpose was to limit as far as possible the ability of the oil companies to profit from the rise in price—for no other reason than simply that they should not profit. It was also an act of mindless greed insofar as its primary purpose having been accomplished, its subsidiary purpose was the enrichment of the U.S. Treasury without knowledge of, or concern for, the consequences.

The effect of this tax was that instead of billions of dollars of revenue simply being diverted from the Arab oil industry back to the American oil industry, a major portion ended up being diverted to the U.S. Treasury. The effect of this in turn was that the American oil industry lacked an equivalent number of billions of dollars of internally generated funds with which to undertake its expansion. Instead, it had to turn to outside sources of funds and borrow heavily. Then, when the collapse in oil prices came, instead of losing back what would have been previously earned “windfall” profits, American oil producers lost borrowed money. And thus many of them went bankrupt who, in the absence of the windfall-profits tax, would not have gone bankrupt, because they would merely have lost back previously earned profits.

A major consequence of this unnecessary tragedy is that the American oil industry today is smaller and less capable of expansion than it would otherwise have been, and thus less capable of further reducing the price of oil.

PART C

UNIVERSAL PRICE CONTROLS AND THEIR CONSEQUENCES

1. The Tendency Toward Universal Price Controls

Price controls tend to spread until all prices and wages in the economic system are controlled—i.e., partial price controls lead to universal price controls.

Universal price controls existed in Nazi Germany. The equivalent of universal price controls exists under socialism, as for example in the former Soviet Union and its satellites. Universal price controls existed in the United States in World War II. They also existed very briefly under President Nixon, when he imposed a ninety-day freeze on all prices and wages in August 1971. They could easily come into existence again in this country, and this time on a long-term basis, in response to any significant worsening of inflation.

The reason partial price controls lead to universal price controls is their destructiveness. We have already seen how partial price controls destroy the industries to which they apply, while causing the uncontrolled industries to flourish. If the government wants to prevent the destruction of the industries it initially brings under controls, it has only three alternatives: It can repeal its controls on those industries, it can subsidize their losses out of the treasury, or it can control the prices that constitute their costs of production. If the government refuses to repeal its initial controls, and if it is unable or unwilling to pay the necessary subsidies, then its only

alternative is to extend its price controls to the prices that constitute the costs of the industries concerned. But then the same story repeats itself, and the government finds that it must bring under controls the prices that constitute the costs of these industries, too, and so on, with the list of controlled prices steadily lengthening.³⁸

For example, consider the case of the oil industry when it was under price controls. The combination of controlled selling prices and rising costs of exploration and development resulting from inflation, meant that the domestic oil industry was progressively being destroyed and was ultimately headed for extinction. In order to prevent these outcomes, the government either had to repeal the price controls on oil (which, fortunately, it did), or subsidize the oil industry to the extent of billions of dollars a year to offset the rise in its costs, or extend its controls to include the prices that constitute the oil industry’s costs, such as the price of steel pipeline and the wages of oil field workers. If it had decided to control these prices, then it would have had to go still further. It would have had to extend its price controls not only further backwards, but in every direction. For example, if it had controlled the price of steel pipeline, then it would have had to extend its controls to all other steel products, such as I-beams, steel sheet, steel cans, and so on, as well as to the price of iron ore, coke, the wages of steel workers, and so forth. If it did not, the effect of its price control on steel pipeline would simply have been to make that one steel product less profitable than the others, and so to destroy its production.

Similarly, if the government had controlled the wages of oil field workers, it would have had to control wages in other occupations, into which the oil field workers might have gone, or into which potential oil field workers might have gone. Obviously, the government would quickly have had to seek to control all wages, because all the different occupations are interconnected. Finally, as the government controlled wages and other prices that constitute costs, it would have had to extend its controls forward to whatever remaining products may have previously escaped controls. Otherwise, the controls on costs would merely have served to make such products more profitable and thereby encouraged their production at the expense of the controlled products.

In this way, price controls have the potential to spread through the economic system like a cancer travelling through the human body’s lymphatic system. All that it takes for this to occur is for controls to reach the point that the government, while still convinced that the controls are necessary, becomes unable or unwilling either to tolerate their effects or to use subsidies to mitigate their effects, and thus turns to the extension of controls to deal with the problems created by the controls already in force.

2. Universal Price Controls and Universal Shortages

The first point which must be understood concerning universal price controls is that they create universal shortages, in which the shortage of each good compounds the shortage of every other good. Under universal price controls, not only does a shortage exist of each good, but also the excess demand for each good spills over and adds to the excess demand for every other good. As illustration, consider again the case of the man who wants a television set but cannot find one at the controlled price. If television sets are the only controlled good, he can find his second choice, a new suit, say. But now, under universal price controls, the suit will probably be as hard to find as his television set. As a result, he must be prepared to settle for his third choice, or, indeed, for his fourth, fifth, or still lower choice, if it is all that is available to him. Eventually, in fact, he will be willing to settle for *any* good that is of greater physical utility to him than the otherwise useless paper money—that is, he will be willing to settle for virtually anything at all.

It should be realized that paper money is of less physical utility than the least valuable good. It does not even make good wallpaper or provide a good fire. The only reason that people do not rush to trade it in for matches or pins or any other physically more useful commodity is that they expect to be able to obtain still more valuable goods for it later on—perhaps later that day, the next day, the next week, or whenever. Price controls and shortages undermine this expectation. They destroy the desire to hold money and eventually make people willing to accept virtually anything in exchange for it.

In these conditions, our man's unsatisfied demand for a television set is *simultaneously* an unsatisfied demand for a new suit and *simultaneously* an unsatisfied demand for goods of still lower choice—it is an unsatisfied demand for anything and everything. And so it is with the unsatisfied demand of everyone else. Thus, it comes about not only that there is an excess demand in the entire economic system, but also that the whole of it is poised ready to strike at whatever goods may be available from any industry. The excess demand facing each industry comes to be not only the unsatisfied demand of those for whom its products are the first choice with the money in question, but also the unsatisfied demand of those for whom its products are the second, third, fourth, and still lower choices. In this way, the excess demand of the whole system comes to exert its pressure against every point in the system. In addition, this excess demand is everywhere further compounded by an enormous hoarding demand for each good.

This discussion, it should be realized, is an actual *description* of conditions as they existed in Soviet Russia. In Soviet Russia, there was a shortage of *everything*. The only exceptions were goods they managed to produce that were of negative utility, such as pots that ruined the taste of food, or clothes that shrank out of all relation to their original size. Apart from such exceptions, everything was chronically in the same state of shortage as gasoline was in this country in early 1974 and in the spring of 1979. In his book *The Russians*, Hedrick Smith, who for some years was the head of *The New York Times'* Moscow Bureau, tells of waiting lines up to a mile long; and of one, to sign up to buy rugs (a once-a-year event in Moscow), that was comprised of between ten and fifteen thousand people lined up four abreast in the winter snow and that lasted for two solid days and nights. Smith reports that Russian women normally spent fourteen hours a week waiting in line just to buy food. He writes that women normally carried shopping bags called “just-in-case bags”—meaning bags for just in case they happened to find something that was for sale and worth buying. The briefcases that Russian men were generally seen carrying served the same purpose.³⁹ I cannot resist quoting one passage because it so eloquently describes the condition of a willingness to buy anything:

Yet despite such ordeals the instinctive reaction of a Russian woman when she sees a queue forming is to get in line immediately—even before she knows what is being sold. Queue-psychology has a magnetism of its own. Again and again, I have been told by Russians that anyone's normal assumption on seeing people up front hurrying to get in line is that there must be something up there worth lining up for. Never mind what it is. Get in line first and ask questions later. You'll find out when you get to the front of the line, or perhaps they'll pass back word before then. A lady lawyer told me she once came upon an enormous line stretching all through the Moskva Department Store, and when she asked those at the end of the line what was on sale, “they said they didn't know or else snarled at me and told me not to interfere. I walked up 20 or 30 yards asking people and no one knew. Finally, I gave up asking.”⁴⁰

Shortages of this type come to exist whenever universal price controls are in force for any extended period of time.

Excess Demand and Controlled Incomes

It is necessary to deal with a difficulty that many people have in understanding how excess demand can exist under universal price controls. Many people reason in the following way: The main source of demand for consumers' goods, they say, is incomes, especially wages. But under universal price controls, everybody's wages, interest, dividends, and so on are controlled. Therefore, people ask, how can demand be rising and a problem of

excess demand be created?

The answer to this question is that excess demand is created by virtue of an expansion in the quantity of money, and that the limitation of incomes is irrelevant.

In order to understand this point as clearly as possible, consider the case of a hypothetical small economy with \$10,000 of total spending, 1,000 units of supply, and a general price level of \$10 per unit. Assume that the \$10,000 of spending in this economy is the result of \$10,000 of incomes. Assume further that when price controls are imposed in this economy, incomes are frozen at a total of \$10,000. Nevertheless, demand in this economy can grow progressively more excessive—in the following way. Assume that the government decides to spend \$1,000 out of newly created money. The price of what the government buys is controlled at \$10 a unit. Consequently, the government buys 100 units of the economy's supply. This leaves 900 units of supply for the citizens. These 900 units are controlled at a price of \$10 per unit. This means that the most it is possible for the citizens to spend in buying them is \$9,000. Nevertheless, the citizens want to spend \$10,000—their incomes. Clearly, the citizens have \$1,000 of unspendable income. What has happened is that the government's spending of \$1,000 out of newly created money has displaced \$1,000 of spending by the citizens and has made \$1,000 of the citizens' incomes back up on them as surplus, unspendable funds.

This phenomenon can grow progressively worse from year to year. We have just seen the government spend \$1,000 and the citizens spend \$9,000. This means that businesses have taken in \$10,000 of sales revenues and in the second year are again able to pay out \$10,000 of incomes. But now, these \$10,000 of incomes are added on to \$1,000 of surplus unspendable income from the year before. This year, therefore, the citizens would like to spend \$11,000 rather than \$10,000. If the government again spends \$1,000 out of newly created money, the citizens will again be able to succeed in spending no more than \$9,000. Thus, there will now be an excess demand of \$2,000, and in the third year it will be \$3,000, and so on. In this way, the shortages grow worse from year to year. It is not too long before people are ready to buy anything.

This example, incidentally, helps to show why price controls do not create severe shortages in the very moment they are introduced. When the controls are first imposed, the existing prices are the proper prices. In fact, they may even have been raised somewhat in anticipation of the controls being imposed. It takes time for these prices to become outmoded—both by continuing inflation and by all the other forces acting to bring about changes in supply, demand, and cost. The longer the

controls remain in force, the more serious their consequences become, because the more out of line do the controlled prices become in relation to the potential free-market prices that would exist if the controls were repealed.

3. The Destruction of Production Through Shortages

The government's purpose in imposing universal price controls is to assure an adequate rate of profit to the vital industries it initially brings under controls. For this reason it imposes controls on the prices that constitute the production costs of these industries. It extends controls to the selling prices of all other industries in order to restrain their rate of profit in relation to that of the controlled industries.

It should be realized that it is perfectly possible under universal controls for all industries to be guaranteed not only approximately equal rates of profit, but rates of profit that by historical standards are relatively high in nominal terms. This is possible because the government controls all the prices that constitute costs, including wages, which are the fundamental element in costs. Nevertheless, no matter how high the nominal rate of profit the government allows, vital industries are still destroyed, and production is disrupted far more seriously than under partial price controls.

What destroys production under universal controls is the consequences of the shortages they create.

In Part B of the present chapter, we saw a variety of ways in which shortages disrupt production under partial controls. I will briefly recount them because all of them apply under universal controls.⁴¹ (It should be recalled in this recounting, by the way, that anything that acts to raise costs implies a decline in production.⁴²)

- (1) Shortages make buyers impotent and thereby remove the incentives of sellers to provide good quality and service. As a result, quality and service decline and the costs of maintenance and replacement increase.
- (2) Shortages of means of production, such as a material, often force sellers to reduce quality and service and make it necessary to resort to more expensive substitute methods of production.
- (3) Shortages encourage sellers to concentrate on the production of unnecessarily expensive models as a disguised way of raising prices.
- (4) Shortages create a positive incentive to using more expensive methods of production if the government allows the pass-through of higher costs and makes the incurrence of higher costs a source of higher profits.
- (5) Shortages result in delays in production.
- (6) Shortages cause hoarding and the construction of additional storage facilities.

(7) Shortages cause the waste of time in searching for supplies.

(8) Shortages create chaos in the geographical distribution of a good among local markets—for example, gasoline during the oil shortage.

(9) Shortages create chaos in the distribution of a factor of production among its various uses in production—for example, crude oil in the production of the various oil products.

Under a system of universal price controls and universal shortages, these elements of chaos apply to all industries, instead of just a few industries. In addition, they apply more strongly to each industry than if that industry were the only industry under price controls, or if price controls were confined to it and just a few others.

First of all, the excess demand confronting each industry is far greater than under partial price controls, because it is compounded by the excess demand for all other products, as we have seen. The greater severity of the shortage of a product under universal controls creates correspondingly more severe problems in connection with that product. As just one illustration, consider the case of cotton and cotton products. If the prices of cotton and cotton products were the only controlled prices in the economic system there would be a problem of using too much cotton to produce shirts, say, and not enough to produce other cotton products, or vice versa. Because, similarly to what we saw earlier in this chapter in the case of crude oil, there would be a shortage of each cotton product.⁴³ Thus more of any one cotton product, such as shirts, could be produced at the expense of the others without reducing its price and profitability, until its particular shortage was totally eliminated. Yet if shirts, cotton, and the other cotton products were the only controlled goods, the increase in shirt production would be limited by the fact that people could spend their money on other goods. Beyond a point, people would be willing to buy additional shirts only at prices that made any further increase in shirt production unprofitable, however low the price of raw cotton might be controlled.

But if *everything* is controlled, and people find no other goods available on which to spend their money than shirts, there is no reason why they would not buy enough shirts to have two or three new ones to wear every day, if there were that many available. People would be willing to go on buying more shirts just so long as extra shirts had a physical utility greater than that of paper money. They would be willing to buy them as a source of cleaning rags, buttons, pins, or whichever, that otherwise might be unobtainable. They would buy them merely to hold as a store of value for the future, because holding them would be better than holding the otherwise unspendable paper money.

The principle that emerges is that under universal controls *it becomes practically impossible to eliminate the shortage even of an individual good by means of expanding its production*, because each good is confronted with the excess demand of the whole economic system.

There is a second reason why the elements of chaos connected with partial controls must apply more strongly under universal controls. This is the fact that *each industry must suffer the consequences of shortages in its capacity as a buyer*. Indeed, it must suffer them in everything it buys. For example, under universal controls, not only does chaos reign for the customers of the oil industry, but the oil industry itself now encounters the same chaos in its own purchases of pipeline, drilling equipment, trucks, tankers, and labor services. Whatever problems the oil industry had before are now intensified. And, of course, in accordance with the principle we just developed, the excess demand confronting the oil industry is radically expanded by the spillover of unsatisfied demand from every other fuel and chemical for which petroleum products could substitute; it is also expanded by the sheer desire of people to own any storable physical good in preference to unspendable paper money.

Not only do universal price controls spread chaos through the whole economic system, and intensify it at every point, but they add a wholly *new dimension* to the chaos, that we have not previously encountered. Namely, *they create chaos in the allocation of capital and labor*, the two elements of production required by every industry. This chaos exists because the shortages of consumers' goods create a ready and waiting employment for more capital and labor in every industry. As a result, the distribution of capital and labor among the various industries is made random. Capital and labor are made to stand in the same relation to all the different industries that we have seen crude oil or raw cotton stand in relation to their respective products. What this means is that capital and labor can be withdrawn from any industry and placed in any other industry, and there is no effect on the rate of profit anywhere. If capital and labor are withdrawn from any industry, price controls prevent prices and profits in that industry from rising. If additional capital and labor are invested in any industry, shortages prevent prices and profits in that industry from falling—all that happens is that the shortage in the industry is reduced. For example, if capital and labor are withdrawn from making paper and transferred to making pots, price controls prevent the price and profitability of paper from rising, while shortages prevent the price and profitability of pots from falling.

The consequence of this state of affairs is that production from industry to industry becomes utterly chaotic.

Not only can any product of crude oil be randomly expanded at the expense of any other product of crude oil, not only can any product of cotton be randomly expanded at the expense of any other product of cotton, but any product anywhere in the economic system can be randomly expanded at the expense of any other product anywhere else in the economic system. The chaos is total.

Let us consider the significance of this. Assume the consumers would prefer to have more shoes and fewer shirts. Under price controls, they cannot bid up the prices of shoes and increase the profitability of shoe production. At the same time, as a result of universal shortages, they will not decrease their purchase of shirts, because they have no alternative use for the money. In fact, in this situation it is perfectly possible that capital and labor could be withdrawn, unchecked, from shoe production, which the consumers want more of, and added on, unchecked, to shirt production, which they want less of—that is, that the *exact opposite* of the consumers' wishes could occur. For if this perverse result did occur, price controls would prevent the price and profitability of shoes from rising to stem the withdrawal of capital and labor from the shoe industry. At the same time, the existence of a shortage would prevent the price and profitability of shirts from falling to stem the inflow of capital and labor into the shirt industry.

Indeed, this perverse result is not only possible, but fully as likely as that the consumers will get the result they want. Under universal price controls, there is no longer any connection between the consumers' preferences and business firms' profits or losses. In an economy in which there are universal shortages, the consumers are ready to buy *anything*. And that makes it possible for businessmen to produce *anything*. I leave it to the reader's imagination to think of what kind of deterioration in quality and service can take place in this kind of situation, and of all the other inefficiencies that can exist.

It should already be clear that the extent to which this perverse process can be carried, of consumers getting goods they want less at the expense of goods they want more, has no limits under universal price controls. No matter how bad the shortage of a particular good becomes as the result of a decrease in its production, price controls prevent its production from becoming more profitable. No matter how much the production of a particular good is increased, its shortage is so severe that practically no amount of additional production will eliminate it, because its shortage reflects the spillover of unsatisfied demand from the whole economic system.

In this way, universal price controls have the effect of flooding people with shirts, while making them go barefoot, or inundating them with shoes, while making them

go shirtless; of giving them enormous quantities of writing paper, but no pens or ink, or vice versa; of giving them food, but no clothing, or clothing, but no food; of giving them toothpaste, but no soap, or soap, but no toothpaste; indeed, of giving them any absurd combination of goods. Moreover, at any moment, the positions of the goods can be reversed, with the relatively abundant ones suddenly disappearing, while the ones previously impossible to find suddenly appear in comparative abundance.

These conditions are not a mere theoretical projection. They were the normal, chronic conditions of Soviet Russia ever since the Communist Revolution. There was no connection in Soviet Russia between production and the desires of the consumers, and practically everything produced for the individual consumers in Soviet Russia was, in the words of Hedrick Smith, "simply junk".⁴⁴

This kind of chaos in production is the source of drastic declines in production.

Merely giving consumers unbalanced combinations of goods is itself equivalent to a major decline in production, for it represents just as much of a loss in human well-being. For example, imagine that a dozen shirts represents the same physical volume of production as three new pairs of shoes, in terms of the capital and labor that must be employed to produce them. Suppose further that what a person wants each year is a dozen shirts plus three pairs of shoes. If he ends up having to settle for two dozen shirts and go barefoot, he is much worse off than if he could have gotten eight shirts and two pairs of shoes, or even just four shirts and one pair of shoes. The same overall volume of physical production becomes equivalent to a smaller volume of physical production by virtue of its being improperly proportioned among people's different wants and needs.

However, this kind of chaos in production does not merely cause chaotic combinations of consumers' goods. It also causes chaotic combinations of capital goods. And in so doing, it reduces the economic system's overall physical ability to produce.

An economic system's ability to produce does not depend merely on the quantity of its capital goods, but, no less, on *the proper apportionment of that overall quantity among the various specific types of capital goods*. If, for example, the steel industry is unduly expanded at the expense of the coal industry, say, the economic system's subsequent ability to produce will be impaired: not only the extra steel mills, but part of the *existing* steel mills may be inoperable for lack of fuel. In the same way, if the coal industry is unduly expanded at the expense of the steel industry, not only the new coal mines, but part of the previously existing coal mines may be inoperable because of a lack of steel products such as

structural supports and drills. An economy's overall ability to produce must be thought of in terms analogous to the functioning of an organism. It depends on the smooth coordination and adjustment of all of its parts. Like a human body, whose total performance cannot exceed the power of its brain, heart, lungs, or any other vital organ, the overall performance of an economic system cannot exceed the power of any one of a large number of vital industries. If some are unduly expanded at the expense of others, the effect is to reduce the functioning of the whole. Indeed, every malproportion has serious consequences.

Consider the devastating effects on production not only of disproportions among whole major industries, like steel and coal, but of disproportions within the output of individual industries—for example, the production of too many trucks to haul farm products and of not enough tractors to harvest them. Consider the effects on production of disproportions in the production of just a few key products here and there—like ball bearings, lubricants for machinery, spare parts, even ordinary screws, and so on. A shortage of any one of these items, or a shortage of one special type of these items, such as ball bearings of a particular size, must cause a widespread paralysis and the grossest inefficiencies in production. And, of course, improper geographical distribution of these or any other inputs has equally devastating consequences for production; for the mere existence of a thing is of no value if its location prevents the producers who need it from obtaining it. The same is true if anything is unavailable for production because it is being hoarded. These declines, of course, are all further compounded by the declines that result from producers just not having to care any longer about the quality of their products or about economies in producing them.

Again, this chaos is not a mere theoretical projection, but an actual description of the chronic conditions of Soviet Russia. In Soviet Russia, hydroelectric stations were built without generators and without the existence of industries to supply; wheat could not be harvested because the necessary tractors had not been built, or, if they had been built, they lacked spare parts, or were in the wrong place, or quickly became inoperable; factories could not operate because they lacked materials; new buildings and new machines were worthless, because of shoddy construction due to lack of care or lack of the necessary materials.⁴⁵

Now the declines in production resulting from all of these causes tend to be *self-reinforcing and cumulative*. For in the course of production, capital goods are physically consumed; i.e., materials and fuel are used up, and machinery and buildings wear out. If production is to be maintained, the capital goods consumed in production

must be replaced. The only source of replacement, however, is production itself; i.e., the capital goods consumed in production in an economic system can be replaced only out of that system's production. But if that production declines sufficiently, because of economic chaos, then it will not be possible to reproduce the capital goods consumed in production. As a result, the stock of capital goods will fall. Once that happens, production must decline further, because it will be carried on with fewer capital goods. If the smaller supply of capital goods is used as inefficiently as was the larger supply, because of continuing chaos in production, it will not be possible to replace the smaller supply of capital goods either. Thus, once again production will decline. This process, of less production causing fewer capital goods causing less production, can go on until the economic system is carried back all the way to the level of barbarism.

To make this process more concrete, just think of the fact that in the course of production such things as steel mills, cement factories, freight cars, and so on are wearing out and must be replaced. The only way to replace them is out of the economy's current production. If that production declines sufficiently, because of economic chaos, then it will not be possible to replace them. The result will be that in the future, production will have to be carried on with fewer steel mills, cement factories, and so on. And then even the smaller number of steel mills, etc., will not be able to be replaced, because, given the continuation of chaos, the output that is obtained from them will be too low.⁴⁶

Special consideration must be given to the shortage of labor that universal price controls create. For the labor shortage introduces a second powerful factor making for a self-reinforcing, cumulative decline in production.

Under universal controls, every industry is eager to employ more labor, because whatever extra products it can produce with more labor will be snapped up by goods-hungry buyers. In addition, the labor shortage is intensified by the declines in efficiency that price controls create, because these declines in efficiency mean that it takes more labor on the average to produce a unit of goods. As a result of the labor shortage, employers are even led to "hoard" labor, that is, keep it on the payroll in idleness or semi-idleness in order to have it available when they need it. This, of course, only intensifies the labor shortage.

What is of special importance is that the labor shortage not only exists because of an excess demand for labor, but it also very soon becomes compounded by a *falling supply* of labor. The supply of labor begins to fall as a result of the shortages of consumers' goods. *These shortages destroy the incentive to work*. As people accu-

multate surplus, unspendable income, it begins to occur to them that they need not earn money they cannot spend. They lose the incentive to advance, because earning more money is useless to them. They cease to care about being fired, because not only can they immediately find another job if they wish it, but the loss of income they cannot spend does not affect them. They begin to do their jobs badly. They become willing to settle for lower-level, less demanding jobs that pay less. They quit their jobs altogether and live off their forced savings for extended periods before taking another job. All of these things represent a decline in the supply of labor. Of course, they also cause a major decline in production and thus in the supply of consumers' goods. This decline in the supply of consumers' goods resulting from the decline in the supply of labor makes the shortages of consumers' goods still worse and thereby further reduces the incentives to work, which, of course, causes even worse shortages. And so it goes, until in fairly short order production must come to a total halt.

Again, it is worth noting that the economy of Soviet Russia was characterized by a labor shortage, in which factory managers "hoarded" labor in order to be sure of fulfilling their quotas under the official economic plan. The shortages of consumers' goods in Russia also contributed to the labor shortage.⁴⁷

The Prosperity Delusion of Price Controls: The World War II "Boom"

Something that is truly remarkable about universal price controls is that, at least in their earlier stages, they can create a delusion of prosperity, even while production is becoming chaotic and on is the road to collapse. The reason for this is that under universal price controls any businessman can find a ready and eager market for any merchandise, no matter how poorly it is produced. All he has to do is produce something of greater physical utility than paper money. In the process, he can even make large nominal profits, simply by virtue of the government having controlled at an appropriate level the prices that constitute his costs. By the same token, the labor shortage makes it possible for any worker to obtain immediate employment in any occupation for which he is even remotely qualified. To those who confuse going through the motions of production with real production, and who confuse the earning of mere paper money with the acquisition of real, physical wealth, this situation looks like prosperity. What they see is that business is humming, everyone is employed who cares to be, and everyone is making money.

Just this situation characterized the United States during World War II. The combination of massive inflation to pay for the war, and universal price controls to hide

the symptoms of the inflation, quickly produced widespread shortages, including a labor shortage. Most people mistook this situation for prosperity.

Nevertheless, despite a superficial appearance of prosperity, the real standard of living of the American people fell drastically during World War II. It fell to a level far below the worst years of the depression. In the worst years of the depression, three-fourths of the American labor force were employed, and everyone who was working could buy anything he wanted commensurate with his earnings. During World War II, *no one* could buy a new car, a new house, or a new major appliance of any kind: the government prohibited their production altogether. In addition, many of the most common, everyday goods simply became unobtainable or obtainable only with great difficulty—such as chocolate bars, chewing gum, sugar, meat, nylon stockings, gasoline, rubber tires, and so on. The goods that were obtainable badly deteriorated in quality—everyone recognized the difference between what they called "prewar quality" and "wartime quality."

People believed they were prosperous in World War II because they were piling up large amounts of unspendable income—in the form of paper money and government bonds. They confused this accumulation of paper assets with real wealth. Incredibly, most economic statisticians and historians make the same error when they measure the standard of living of World War II by the largely unspendable "national income" of the period.

The controls did not last long enough in this country to wreck the economic system. Their effect was further mitigated by the fact that we entered the war with mass unemployment and a large amount of idle plant capacity. The absorption of these factors into production made it possible to offset much of the wastes and inefficiencies resulting from the controls. They constituted a kind of temporary reserve fund, as it were, out of which much of the costs of the controls were met.

Also, during the war, people were highly motivated by considerations of patriotism, and were not only willing to tolerate the hardships imposed by the war, but actually to work harder and longer. Many of them reasoned that if the soldiers at the front could risk their very lives in the defense of civilization, they could do with fewer goods and put in an extra effort at work. Finally, no one regarded the controls as a permanent institution—everyone looked forward to a quick end to the war and to the opportunity to spend after the war.

Such things, however, can at best only delay the full consequences of universal controls. In the circumstances of the present and of the foreseeable future, moreover, no such mitigating factors are present.

4. Socialism on the Nazi Pattern

In an effort to deal with the chaos it creates through price controls, the government adopts further measures: *it seizes control over production and distribution.*

For example, during the oil shortage of 1973–74 a new government agency—the Federal Energy Administration (now the Department of Energy)—was established. This agency had the power to tell the various oil companies how much of each of the various petroleum products they were to produce and to which industries, firms, and regions they were to distribute those products. Thus, government officials decided how much refining capacity should be devoted to producing gasoline, how much to producing heating oil, jet fuel, propane, kerosene, and so forth. In the process, government officials decided which industries dependent on the various petroleum products would obtain supplies, and to what extent. They decided the distribution of each individual petroleum product among its various uses, such as how much gasoline would go to truckers, how much to bus lines, and how much would be left for passenger automobiles. They decided which firms in each industry would get how much of the product allotted to that industry. For example, in the airline industry, they decided that each airline would get 80 percent of the jet fuel it had consumed in the previous year. They decided which geographical areas would get how much of each product. For example, they decided how much gasoline went to New Jersey and how much to New York. And they were about to decide how much gasoline and heating oil went to each individual consumer—for example, the plan to give every licensed driver over eighteen a fixed monthly ration of gasoline by issuing coupons with the picture of George Washington on them.

In addition, government officials made it their business to look into the methods of production employed by the users of oil products. For example, they began to try to force electric utilities to switch from burning oil to burning coal, in order to reduce oil consumption. (Often, these were the same utilities that only a short time before the same government had forced to convert to oil, under the influence of the ecology movement.) As part of this process, they reduced highway speed limits, which must be viewed as an interference with methods of production insofar as it applies to trucks and buses or any form of travel for business purposes.

All of these further interferences were an unavoidable response to the chaos in the oil industry, given the fact that the government was not prepared to abandon its controls over oil prices. Price controls and shortages had made the output of the oil industry and the subsequent distribution of that output utterly chaotic. The govern-

ment took control of production and distribution in the oil industry in an effort to deal with this chaos.

Now under a system of universal price controls, such as existed in World War II, the government is led to seize control over the production and distribution of *every* commodity. The government thus comes to decide not only all prices and wages, but how much of each item is produced, by what methods, in what locations, and to whom it is distributed. The government fully controls all the inputs that each firm receives, how it combines those inputs into outputs, and what it does with the outputs.

There is only one appropriate name to describe this state of affairs of full government control over production and distribution. And that is *socialism*. In seizing control over all production and distribution, the government fully socializes the economic system.

The reason the system must be called socialism is because, in fact, *the government exercises all of the powers of ownership*. The meaning of ownership is the power to determine the use and disposal of property. If the government determines what a firm is to produce, in what quantity, by what methods, and to whom it is to sell its output and at what prices, then it is the government that determines the use and disposal of the firm's property. The government, therefore, becomes the real owner of the firm—the *de facto* owner. The nominal owners recognized by the law—that is, the firm's stockholders (and also the board of directors chosen by the stockholders, and the managers appointed by the board of directors)—are reduced to the status of government functionaries, compelled to carry out the government's orders. The fact that the stockholders may be allowed to continue to draw dividends is irrelevant. The status of these stockholders is essentially no different than if the government had openly nationalized their property and given them government bonds on which they received interest.

This system of *de facto* socialism, carried out under the outward guise and appearance of capitalism, in which the legal forms of private ownership are maintained, has been aptly characterized by von Mises as socialism on the German or Nazi pattern.⁴⁸ The Germans under Ludendorff and Hindenburg in World War I, and later under Hitler, were the foremost practitioners of this type of socialism. (The more familiar variant of socialism, in which the government openly nationalizes the means of production and establishes socialism *de jure* as well as *de facto*, von Mises calls socialism on the Russian or Bolshevik pattern, after *its* leading practitioners.)

It cannot be emphasized too strongly that Nazi Germany was a socialist country and that the Nazis were right to call themselves National *Socialists*. This is something everyone should know; yet it appears to have been overlooked or ignored by practically all writers but von

Mises. In Nazi Germany, the government controlled all prices and wages and determined what each firm was to produce, in what quantity, by what methods, and to whom it was to turn over its products. There was no fundamental difference between the Nazis and the Communists. While the Communists in Russia wore red shirts and had five-year plans, the Nazis in Germany wore brown shirts and had four-year plans.

There is a further point that must be made about the use of the term “socialism.” Socialism means *an economic system based on government ownership of the means of production*. On the basis of this definition, not only must Nazi Germany, a country usually not recognized as socialist, be categorized as socialist, but other countries, usually thought of as *being* socialist, must *not* be categorized as socialist—for example, Great Britain, Sweden, and Israel when they were under the rule of so-called labor governments.

In these three countries, the economic system has always been characterized by private ownership of the means of production—not only *de jure*, but *de facto* private ownership. This private ownership, to be sure, has labored under all sorts of restrictions and prohibitions, but still it has been private ownership, and production in these countries has been carried out primarily at the initiative of private owners for the sake of private profit. The philosophy of the ruling political parties of these countries may have been socialism and socialism may have been their ultimate goal, but their actual practice, up to now, has not been socialism. The correct description of these economies is von Mises’s expression “hampered market economy,” and that description applies to the economy of the United States, too. For the sake of brevity, such an economy can be referred to as a “mixed economy,” provided it is understood that what is meant is an economy based on private ownership of the means of production but more or less severely hampered by an extensive list of socialistically motivated acts of

government intervention.

In this last connection, it should be realized that the existence of isolated socialized industries, such as the postal service and the railway network, does not warrant characterizing a country as socialist. So long as such industries operate in the context of a market and market prices based on a foundation of private ownership of the means of production and the profit motive, they represent, in effect, merely a blemish on an otherwise capitalist body. The existence of such industries belongs under the heading of socialistically motivated acts of government intervention and properly serves to categorize the economy of a country as a hampered market economy, but not as a socialist economy.⁴⁹

The only truly socialist countries in the world today are Communist China and the other remaining members of the Communist bloc, such as Cuba and North Korea. Perhaps several of the East European countries, the surviving “republics” of the former Soviet Union, and possibly some of the so-called third-world countries should also continue to be classified as socialist. But no other countries are in fact socialist. Indeed, to the extent that growing market activity now exists in virtually all of the East European countries and the various former Soviet Republics, the classification even of these countries as socialist becomes increasingly dubious. More and more, their status appears to be that of primitive market economies, in which economic activity takes place in the absence of clearly defined or legally protected private property rights, but nevertheless on the basis of individual initiative, motivated by private profit. Hopefully, within the next few years, no existing country will warrant being described as socialist. Indeed, it appears that in at least one major province of Communist China, *de facto* private ownership of the means of production and a market economy more advanced than those of most former members of the Communist bloc, have already come into existence.

Notes

1. The quantity theory of money is elaborated at length on pp. 503–506. The demonstration that it is the only possible valid explanation of a sustained, significant rise in prices occupies the whole of pp. 895–922.

2. See above, p. 152.

3. This equation and its implications are developed and elaborated below, pp. 505–506 and 897.

4. Actually, I will show later that falling supply can practically never be the cause of a sustained significant rise in prices and that at no time can it be the cause of the full *complex* of symptoms that people complain of in discussing inflation, such as the enormously greater number of prices rising compared

with the number of prices falling and the effects on the relationship between debtors and creditors. In addition, I will show that falling supply is itself usually a consequence of rapid inflation. Concerning these points, see below, pp. 897–907.

5. For the explanation of this phenomenon, see below, pp. 519–526.

6. On these points, see below, pp. 895–922, which show conclusively why the quantity theory of money is the only valid explanation of an inflationary rise in prices, and why any element of truth in any alternative explanation of rising prices serves only to confirm the quantity theory of money.

7. Statistics of the money supply are published every Friday in

The New York Times and *The Wall Street Journal*. Historical statistics are available from the Board of Governors of the Federal Reserve System, Washington, D.C. The Federal Reserve Bank of St. Louis regularly publishes data showing the trend of growth in the money supply on a short-term and long-term basis.

8. For a further, related discussion of the effects of price controls on natural gas, see George Reisman, *The Government Against the Economy* (Ottawa, Ill.: Jameson Books, 1979), pp. 130–132.

9. Cf. above, p. 191.

10. On these points, see John Stuart Mill, *Principles of Political Economy*, Ashley ed. (1909; reprint ed., Fairfield, N. J.: Augustus M. Kelley, 1976), pp. 706–709. See also above, p. 192 and pp. 217–218, n. 19.

11. For the rebuttal of those fallacies see above, pp. 192–194.

12. *New York Times*, April 28, 1978, pp. 1, D9.

13. The explanation of why inflation reduces or altogether eliminates the real rate of return on capital is provided below, pp. 930–938.

14. Indeed, as previously pointed out, the hysteria of the ecology movement has caused the government of the State of New York to deprive its citizens of the benefit of an actually existing, brand new major atomic power plant—the Shoreham plant on Long Island. See above, pp. 66–67.

15. *New York Times*, January 29, 1977, p. 22.

16. For a discussion of the various ways in which inflation reduces the real rate of profit, see below, pp. 930–937.

17. See below, pp. 931–933. In the case of inventories, there is some relief in that it is possible for businesses to choose to calculate their costs for tax purposes on the basis of the cost of the inventory acquired last rather than first—i.e., the so-called “Lifo” system (last in, first out) rather than the customary “Fifo” system (first in, first out). In the case of fixed assets, however, there is no such palliative.

19. See Ludwig von Mises, *Socialism* (New Haven: Yale University Press, 1951), pp. 40–42, 500–504; reprint ed. (Indianapolis: Liberty Classics, 1981). See also below, pp. 296–300, which greatly elaborate on the points just made.

20. See above, pp. 228–230.

21. *New York Times*, April 11, 1974, pp. 49, 55.

22. Reported improvements in fuel economy are largely the result of compelling manufacturers to produce smaller, lighter-weight cars.

23. It is closely associated with what I described earlier as the Eloi mentality. See above, pp. 110–112.

24. Cf. above, pp. 23–26.

25. For a rebuttal of the closely related charge that a free economy lacks freedom of competition and freedom of entry, see below, pp. 375–376. For further discussion of the concepts of freedom and freedom of competition and a refutation of the related tissue of fallacies that constitute the doctrines of “oligopoly,” “monopolistic competition,” and “pure and perfect competition,” and of the charge that a free economy lacks “price competition,” see below, pp. 425–437. See also the discussion of the concept of freedom on pp. 21–27, above.

26. As will be seen, under universal price controls, it is possible for the controls to build in a substantial rate of profit. Even so,

potential competition would not be a factor, because in the context of universal price controls, the shortages are so severe that even if new suppliers could enter any given industry, the effect would not be to eliminate the shortage faced by the customers of that industry. At the same time, the effect would be to make shortages elsewhere in the economic system more severe. On these points, see below, p. 257.

27. *New York Times*, February 5, 1974.

28. These results are reinforced by the fact that the more economical models, being more popular and therefore selling faster, tend to carry lower profit margins in a free market than do the higher priced models. For example, \$1 million of capital invested in a fast-moving inventory of low-priced models may generate \$2 million of sales revenue in a year, while the same sized capital invested in a slow-moving inventory of high-priced models may generate only \$1 million of sales revenue in a year. In order to earn the same rate of profit on capital, say 10 percent, when invested in either inventory, it is only necessary to have a 5 percent profit margin on the low-priced models, while a 10 percent profit margin is required on the high-priced models. If price controls are imposed and costs rise by any given percentage, the reduction in profit margins will be more severe in the case of the low-priced models. For example, a 5 percent rise in costs will just about totally eliminate profits on the low-priced models, while it will roughly halve them on the high-priced models. This too tends to cause the discontinuance of low-priced models ahead of high-priced models.

29. For a more forceful demonstration of this point, see below, pp. 254–256.

30. See above, pp. 205–206.

31. I am indebted to von Mises for this point and for the example used to illustrate it. See Ludwig von Mises, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery Co., 1966), pp. 762–764; *Socialism*, pp. 532–534; *Planning For Freedom*, 4th ed. (South Holland, Ill.: Libertarian Press, 1980), pp. 73–75.

32. The additional expenditure on the uncontrolled goods is equal to the funds that the sellers of milk are prevented from receiving by virtue both of the artificially low, controlled price of milk and the reduced production of milk.

33. Because the Soviet Union was always nothing more than an illegitimate extension of Russia—the Russian Empire—I follow the practice of referring to it simply as Russia or Soviet Russia, though in view of the recent breakup of this empire, it is sometimes necessary to distinguish Russia from the former Soviet Union as whole.

34. Of course, the government is capable of forcing people to sleep in the streets, by prohibiting landlords from providing housing in the limited size and quality people can afford. Where they are local, such prohibitions are accompanied by a spillover effect of their own, which makes conditions worse in areas free of such restrictions. On these points, see below, pp. 384–385.

35. It should not be forgotten, of course, that a major portion of the increase in price paid to the American oil companies was not actually received by them but was taken by the government in the form of the so-called windfall-profits tax.

36. This is written in the fall of 1993.

CHAPTER 8

THE DEPENDENCE OF THE DIVISION OF LABOR ON CAPITALISM IV: SOCIALISM, ECONOMIC CHAOS, AND TOTALITARIAN DICTATORSHIP

PART A

THE CHAOS OF SOCIALISM

1. Socialism

From this point on, our discussion of the consequences of price controls becomes a discussion of the consequences of *socialism*.

In studying the consequences of socialism, it does not matter whether we study an economy that has arrived at socialism through price and wage controls or one that has arrived at socialism openly, through the explicit nationalization of all industry. Nor does it matter whether socialism has been brought about peacefully, through lawful processes and the observance of democratic procedures, or by means of a violent revolution; it also does not matter whether the professed goal of socialism is universal brotherly love or the supremacy of a particular race or class. Economically, the system is the same in all these cases: *The government owns the means of production and it is the government's responsibility to decide how they are to be used.* Consequently, everything I will have to say about socialism will apply to all variants of socialism: to the socialism of the Nazis, to the socialism of the Communists, and to the socialism of the Social Democrats, such as the late Norman Thomas. What I

have to say will apply to any economic system actually based on government ownership of the means of production. Of course, it will not apply to countries such as Great Britain, Israel, and Sweden, which, though governed for extensive periods by political parties espousing the philosophy of socialism, did not implement socialism as their actual economic system. Of course, it may apply to one or more of those countries in the future. Most importantly, it will apply to the economic system of the United States, should price controls once again be imposed and made universal and the government seize control over production and distribution in this country, which is more than possible at some point in the years ahead, given the profoundly inflationary nature of our present monetary system.

2. The Essential Economic Identity Between Socialism and Universal Price Controls

The most important principle to grasp about socialism is that *its economic consequences are essentially the same as those which result from universal price controls.* If socialism is introduced in response to the chaos created by universal price controls, its effect is to perpetuate that chaos; if it is introduced without the prior existence of universal price controls, its effect is to inaugurate that very chaos. This, of course, is ironic insofar as the government uses the chaos created by price controls as

the grounds for its socialization of the economic system. Nevertheless, socialism and universal price controls are fundamentally the same in their economic nature and therefore produce the same effects. It is for precisely this reason that Soviet Russia has so consistently provided such excellent examples of the consequences that follow from universal price controls: Among these examples have been restrictions on the internal freedom of migration and the compulsory sharing of housing, shortages so severe that they result in mile-long waiting lines and people being ready to swoop down on whatever may happen to be available, and, above all, gross inefficiencies in the production and use of capital goods, which radically reduce the overall ability to produce.¹

The essential economic identity between socialism and universal price controls consists in the fact that *both of them destroy private ownership of the means of production and its offshoots the profit motive and the price system.*

Price controls destroy private ownership of the means of production in the very fact of destroying the right to bid and ask prices. In a division-of-labor economy, in which buying and selling are indispensable to production and all other economic activity, the right to bid and ask prices is a fundamental, indispensable right of ownership. Without it, all other rights of ownership are meaningless. For example, the right to own a factory is meaningless if the owner is prohibited from charging or paying the prices required to keep his factory in existence. Essentially, price controls are fully as destructive of the rights of ownership as socialism itself. And, of course, when price controls are compounded by shortages, the government's response to the consequences is to seize total control over the means of production and establish *de facto* socialism.²

Furthermore, *what makes price controls produce the chaos they do is precisely the fact that they interfere with the property rights of businessmen.* Specifically, they prohibit businessmen from using their capitals in the ways that would be most profitable to themselves. If they did not interfere with the right of businessmen to use their capitals in the most profitable way, then they could produce none of their chaotic effects. Try to imagine the government *not* interfering with the businessman's property rights and profit motive, and yet the consequences of price controls developing. Think back to the preceding chapter and recall the following elements of chaos that we saw resulting from price controls: shortages and the destruction of vital industries; the impotence of consumers accompanied by hatred between buyer and seller; the impetus to higher costs; chaos in the personal distribution of goods to consumers; chaos in the geographical distribution of goods among various local markets; chaos in

the distribution of a factor of production among its various products; chaos in the distribution of capital and labor among the various industries.

Consider. All of these elements of chaos result from just one thing: *interference with the businessman's property rights and profit motive.* For example, would businessmen voluntarily sell their goods too cheaply and thus cause shortages? Obviously not. Their property rights must be violated and they must be forced to do so. Would businessmen abandon the production of vital goods if they were free to charge profitable prices for them? Obviously not. Would they drive away customers offering them profitable business? Again, no. Would they run up the costs of production if those costs came out of profits (as they would have to in the absence of price controls and shortages)? Clearly not. Would businessmen saturate some markets at low prices, while starving others offering them high prices? Would they use a factor of production to produce some products to excess at low prices, while producing not enough of other products offering them high prices? Would they overinvest in some industries at low profits or losses, while underinvesting in other industries offering high profits? Again, the answer is clearly no to all of these questions. What makes businessmen behave in these ways is that their property rights are violated and they are thus prevented from doing what is profitable to themselves.

The wider principle that emerges is that the entire price system and all of its laws and harmonies depend on one essential fact: *the observance of private property rights and thus the freedom of businessmen to act for their own profit.* It is private property rights and the profit motive that are the foundation and the motive power that underlie and drive the entire price system. It is they which underlie and actuate all of the benevolent economic laws we observed in our study of the free market, such as the uniformity-of-profit principle, the various principles of price and wage uniformity, the cost-of-production principle, the principle that prices are set high enough to limit demand to the supply, and the principle that factors of production are channelled to their most important employments. All of these laws and all of their benevolent consequences are the result of just one thing: private property rights and the profit motive.

Now socialism destroys all property rights. And with them it destroys the operation of the profit motive and the entire price system.

Socialism produces the same chaotic effects as price controls, *because it destroys the same thing as price controls, namely, the one and only source of economic order and harmony in the world: private property rights and the profit motive.*

The essential fact to grasp about socialism, which

explains why it is essentially identical to price controls, is that *it is simply an act of destruction*. Like price controls, it destroys private ownership and the profit motive, and that is essentially *all* it does. It has nothing to put in their place. Socialism, in other words, is not actually an alternative economic system to private ownership of the means of production. It is merely a *negation* of the system based on private ownership.

3. The Myth of Socialist Planning—The Anarchy of Socialist Production

Of course, socialism is not usually perceived simply as a negation. The first economist fully to grasp the destructive nature of socialism was von Mises, and he has not had many followers.³ Much more often, socialism is perceived as a source of economic order and harmony. In fact, the most popular synonym for socialism is “economic planning.” The belief in socialism’s ability to plan is why a government turns to socialism when confronted with the chaos created by price controls. Indeed, the belief in socialism’s ability to plan may be one of the reasons for instituting price controls in the first place—namely, as a deliberate step leading directly to socialism. Certainly, the belief in socialism’s ability to plan has been a major factor in the popularity of socialism. Without it, it would be difficult for socialism to find supporters.

Nevertheless, a socialist government is helpless to bring order out of the chaos created by price controls. And if price controls do not exist when it assumes power, then it proceeds to create the same chaos as price controls by the very fact of socializing the economic system. For the great joke of socialism, of “planning,” as it is called, is that it *cannot plan*; it *destroys* planning and substitutes chaos.

In order to understand why socialism cannot plan, we must look again at capitalism. This will enable us to form an idea of what is required for economic planning and, therefore, why socialism is incapable of it.

The reader should recall that *under capitalism each individual engages in economic planning*.

I must stress this fact and I am going to give a very extensive list of examples of it, because it is very important and because socialist propaganda has created exactly the opposite impression in the minds of most people. It has created the impression that what individuals do under capitalism is run about like chickens without heads in an “anarchy of production,” and that rational action—planned action—is a prerogative of government. The truth is that each individual under capitalism is engaged in economic planning almost continuously. Unfortunately, as pointed out in Chapter 5, most of us are in the position of M.

Jourdan—the character in the Molière play—who spoke prose without ever knowing it.⁴ We are all engaged in economic planning under capitalism, practically every day, but hardly any of us realize it—least of all, today’s intellectuals. Let us see in just what ways we practice economic planning.

An individual is engaged in economic planning when he plans how much of his wealth and income to save and invest and how much of it to consume; when he plans where to invest it and in what ways to consume it. He is engaged in economic planning, for example, when he plans to put his money in a bank or in the stock market, and in which specific shares in the stock market; when he plans to buy more clothes or a new stereo; even when he plans to drive to work or take the train, instead.

Every businessman under capitalism is engaged in economic planning when he plans to expand or contract the production of any item; when he plans to introduce a new product or discontinue an old product; when he plans to change his methods of production or retain his existing methods; when he plans to build a new factory or not to replace an existing one; when he plans to change the location of his business or let it remain where it is; when he plans to buy new machinery or not; to add to his inventories or not; to hire additional workers or let some of his present workers go.

Every wage earner under capitalism is engaged in economic planning when he plans to seek new employment or to retain his present employment; when he plans to improve his skills or rest content with the ones he has; when he plans to do his job in one particular area of the country, or in one particular industry, rather than in another.

In short, every one of us under capitalism is engaged in economic planning every time he plans any aspect of his personal finances or business affairs. We are engaged in economic planning every time we *think* about a course of action that would benefit us in our capacity as a buyer or seller.

It is simply amazing that all of this planning could be overlooked, and that the socialists have been able to proceed as though capitalism lacked planning. Capitalism *has* planning—the planning of each and every person who participates in the economic system.

Let us observe another, equally important fact, briefly described in Chapter 5: Namely, that the planning of capitalism—which, as I say, takes place on the part of everyone—is based on prices.⁵

Prices have a twofold function in the planning of capitalism. First, *they enable the individual planner of capitalism to perform economic calculations*. That is, they enable him to compute the money cost and/or money revenue of various modes of conduct. If the planner is a

businessman, he weighs a money cost against a money revenue. If he is a consumer, he weighs a money cost against a personal satisfaction. If he is a wage earner, he weighs a money revenue against his personal efforts. *These economic calculations provide a standard of action for the planner under capitalism.* They tell businessmen to produce the products and use the methods of production that are anticipated to be the most profitable. They tell consumers to consume in the ways that, other things being equal, occasion the lowest cost. And they tell wage earners to work at the jobs that, other things being equal, pay the highest wages. Thus, prices are an indispensable guide both to the planning of production and to the living of one's personal life under capitalism.

The second, corollary function of prices is that *they coordinate the plans of each individual under capitalism with the plans of all other individuals.* That is, prices serve to make each individual adjust his own plans to the relevant plans of all other individuals in the economic system. In this way, *capitalism and the price system bring about a harmoniously integrated planning of the entire economic system.* Our whole discussion of the free market's price system demonstrated this process of coordination and mutual adjustment. It is only necessary to say the following, by way of summary of that discussion: Namely, that concern with money revenue makes one adjust to the plans of the prospective buyers of one's goods or services and to the plans of all competing—and even potentially competing—sellers of those goods or services. And that concern with money costs makes one adjust to the plans of all other buyers seeking either the things one buys, the factors of production from which they are made, or alternative products of those factors of production—and to the plans of sellers in their capacity as individuals having definite personal values and preferences. The desire to earn a money revenue leads one to produce things that the buyers want and that are not being produced excessively by other sellers. The desire to limit costs leads one to economize on things to the degree that other buyers value them, or value the factors of production on which they depend, or the alternative products of those factors of production; and also to economize to the degree that the goods or services in question can be provided only at some special inconvenience to the sellers engaged in producing them.

Now socialism, in destroying the price system, destroys the possibility of economic calculation and the coordination of the activities of separate, independent planners. It therefore makes rational economic planning impossible and creates chaos.

As an illustration of the consequences, consider the problems confronting a socialist government in trying to plan the production of a simple item, such as shoes. Shoes

can be produced in varying quantities, in various styles or combinations of styles, and by various methods or combinations of methods, such as by machine or by hand, including the choice between using various proportions of machine or hand production in different parts of the overall process. They can be produced from different materials or combinations of materials, such as leather, rubber, and canvas, and in different geographical locations, again, in both instances, in varying proportions. Under capitalism, all of these choices are determined on the basis of economic calculations. Thus, shoe production as a whole tends to be carried to the point where further production would make the shoe industry relatively unprofitable in comparison with other industries; the styles are those which the consumers are willing to make profitable; the methods of production, the materials used, the geographic locations are all the lowest cost except insofar as they provide special advantages for which the consumers are willing to bear the extra cost.

Under socialism, the lack of economic calculation makes it impossible to make any of these choices on a rational basis. The extent of attempted shoe production is determined arbitrarily—most likely on the basis of some official's judgment about how many pairs of shoes are "necessary" per thousand inhabitants, or some such criterion. Style is determined arbitrarily—according to what suits the tastes of those in charge. The methods, materials, and locations planned must be selected arbitrarily. And then—for reasons that will soon become clearer—the actual carrying out of production, as opposed to what is called for in the plans, may very well have to be undertaken on the accidental basis of the means of production that happen to be available.

Now it must be stressed that the decisions about all of these choices—quantity, styles, methods, and so on—are important not only from the standpoint of the consumers of shoes, *but, no less, from the standpoint of the production of all other goods.* It must be borne in mind that shoe production, or the production of any good whatever, requires factors of production which are thereby made unavailable for other purposes. Shoe production requires labor that could be employed elsewhere. It requires leather or other material that either might be employed elsewhere or which is produced by labor that could certainly be employed elsewhere. In the same way, the tools or machines required, or the labor and the materials used to make them, have alternative employments. Moreover, each of the different choices respecting shoe production makes a *different* combination of factors of production unavailable for alternative employments. For example, shoes produced by hand reduce the number of handicraft workers available for other purposes. Those produced by machine reduce the number of machine makers and the

amount of fuel available for other purposes. Shoes produced in Minsk leave less labor available for other purposes in Minsk than if they were produced in Pinsk, and so on.

It is, therefore, clearly not enough, as most socialists appear to believe, for a socialist government—having inherited or stolen the technology of shoe production—to simply decide how many shoes to produce, determine on a style, quality, method, and locations for production, and then give the orders to produce them. In planning the production of shoes, or any other individual item, a socialist government is logically obliged to consider its effect on the production of *all other items in the economic system*. It is logically obliged to try to plan the production of shoes, or any other good, in a way that least impairs the production of other goods. In drafting its plans for shoe production, a socialist government is obliged to consider the extent of shoe production in relation to the production of all other goods using the same factors of production. It is obliged to consider such questions as whether shoe production might be expanded with factors of production drawn from the production of some other good, and whether the production of that other good might be maintained by drawing factors of production from a third good, and so on.

For example, it must consider whether it would be advisable to use more labor in Minsk for shoes and less for making clothing, say, and perhaps to expand clothing production in Pinsk, at the expense of some third good. It must consider *all* of the industries using *any* of the factors of production used in the shoe industry. It must consider what depends on the output of those industries and what alternative factors of production are available to those industries. Indeed, it must go even further. It must consider all of the industries using the alternative factors of production. It must consider what depends on *their* products, and what further alternative factors of production may be available to *them*. And so on. And at each step, it must consider the possibility of expanding the overall supply of the factor of production in question, and, if so, by what means, where, and at the expense of what.

To make these problems real, let us continue with the example of shoes. In order to plan shoe production rationally, it would be necessary for a socialist government to consider all of the alternative employments of each of the factors of production used to produce shoes. Let us start just with leather. A socialist government would have to consider the alternative employments of leather, such as upholstering furniture and providing belting for machinery. It would have to consider the consequences of having more or less furniture and machinery versus more or less shoes. It would have to

consider alternatives to the use of leather in upholstering furniture and making belting for machinery—for example, various fabrics, and plastic and steel. It would have to consider the alternative uses for the various fabrics and for the plastic and steel, or for the factors of production used to produce them. It would have to consider what depended on those alternative uses, and what substitutes were available for them. It would have to consider whether the total supply of leather, its substitutes, or the substitutes for its substitutes, should be expanded, and, if so, by what means, where, and at the expense of what. Then, of course, the socialist government would be obliged to repeat the same procedure for all of the other factors of production employed to produce shoes, or which potentially could be employed to produce shoes.

All of this raises the insuperable difficulty of socialist planning: *Namely, under socialism, it is necessary to plan the production of the entire economic system as an indivisible whole*. That would be the only rational procedure.

But the planning of the economic system as an indivisible whole is simply impossible.

It would require a superhuman intellect to be able to grasp the physical connections among all the various industries and to be able to trace the consequences of alterations in any one industry on all the others. What would be required for the rational planning of a socialist economy would be the existence of an omniscient deity willing to descend from heaven and assume the management of the socialist economy.

This deity would have to be able to hold in mind at one time a precise inventory of the quantities and qualities of all the different factors of production in the entire economic system, together with their exact geographical locations and a full knowledge of the various technological possibilities open to them. That is to say, it would have to be able to hold in mind at one time all of the millions of separate farms, factories, mines, warehouses, and so forth, down to the last repair shop, together with a knowledge of the quantity and quality of all the machines, tools, materials, and partly-finished goods that they contained, and exactly what they were potentially capable of accomplishing and when.

It would then have to be able to project forward in time all of the different new combinations of factors of production that might be produced out of the existing factors, together with where and precisely when they would come into existence and the technological possibilities that would then be open to them. It would have to be able to make this projection for an extended period of time—say, a generation or more—in order to avoid the possibly wasteful production of machines and buildings lasting that long.

And then, out of all the virtually infinite number of different possible permutations and combinations of what might be produced, it would have to pick one that on some undefined and undefinable basis it considered “best,” and then order it to be undertaken. That would be its economic plan. *That* is what would be required even to begin to duplicate what capitalism accomplishes through the price system.

For observe. Under capitalism, different individuals in combination—that is, when their knowledge is added together—*do know* the precise quantities, qualities, locations, and technological possibilities open to all the various factors of production in the economic system. And everybody’s production is based on the sum of all of this knowledge, because the knowledge is reflected in the prices of all the various factors of production and products. For example, the price of wheat at any given time reflects the knowledge of each owner of wheat concerning the amount, quality, and location of the wheat he owns; it also reflects the knowledge of each user of wheat about the technological possibilities open to wheat. All of this knowledge enters into the supply and demand and hence the price of wheat. It is the same with every other good: its price reflects the sum of existing knowledge about the amount of it available, the technological possibilities open to it in production, and every other relevant consideration. And the future supply, locations, and production possibilities of factors of production are taken into account in the anticipation of their future prices.

The deity needed for the planning of socialism would require intellectual powers even surpassing those I have described. For under socialism any unanticipated event, such as a train wreck, an early snowstorm, a warehouse fire, an unexpectedly bad harvest—even unanticipated favorable events, such as the opposite of all of these—is a calamity, for it requires *the replanning of the entire economic system*. For example, if a tank train carrying a shipment of oil is destroyed, how is the socialist economy to decide where to take out the loss? It would have to look at all of the different uses for oil, all the possible remote consequences of its withdrawal from this or that area of production, and it would have to look at all of the alternative employments of factors of production that might be used to replace the lost oil, and all the permutations and combinations entailed in that, and then decide. By the same token, if, as a result of good fortune, a socialist economy had fewer wrecks of tank trains than anticipated, it would have to replan the entire economic system to find the right use for the extra supply of oil.

Capitalism, on the other hand, as we have seen throughout, responds easily and smoothly to unforeseen changes in economic conditions. Such changes simply bring about a change in the structure of prices and thus generate the

most efficient response on the part of all concerned. Thus, the wreck of a tank train—to continue with that example—acts to raise the price of oil a little. The rise in price diminishes the consumption of oil in its marginal employments and simultaneously encourages its production—and, of course, at the least possible expense to other productive activities. The reason capitalism responds so smoothly and efficiently is that every individual in the economic system is involved in planning the response. Each individual acts on the basis of his knowledge of his own personal or business context, and the actions of all the individuals are harmoniously integrated through the price system.⁶

The essential problem of socialism is that it requires economic planning to take place without benefit of a division of intellectual labor. It requires that one man (the Supreme Director), or each of several men (the Supreme Board of Directors), hold in his head and utilize the knowledge that can be held and utilized only by millions of separate individuals freely cooperating with one another on the basis of private ownership of the means of production and its offshoots the profit motive and the price system. The essential economic flaw of socialism is that in destroying these basic institutions of capitalism, it destroys the foundations of the intellectual division of labor that is indispensable to rational economic planning.

As I say, therefore, the planning of the economic system as an indivisible whole—by single individuals—let alone its continuous replanning in response to every unforeseen change, is simply impossible. The ruler of socialism, after all, is simply not an omniscient deity.

As a result, although it is called “central planning,” socialism can never have anything even approaching a rationally integrated plan for the entire economic system. In reality, the actual planning of socialist countries is undertaken by separate government ministries, each responsible for different industries or regions. Even the individual factories undertake part of the planning process. The plans of these separate ministries and individual factories are only superficially integrated into an economy-wide plan. In this sense, the actual planning of socialism must be called “decentralized planning.” There is no alternative to decentralized planning, because it is simply impossible for any one individual to try to plan everything. Decentralized planning exists as soon as two or more people assume separate responsibilities in the planning process.

However, the decentralized planning of socialism necessarily causes chaos. Because without a price system—without the foundation and mainspring of the price system, i.e., private ownership of the means of production and the profit motive—the individual planners must operate at cross purposes. First of all, there is nothing to stop their

various discoordinated plans from presupposing the availability of the same factors of production. In such conditions, the execution of any plan necessarily absorbs factors of production whose absence then makes the execution of other plans impossible. For example, if the shoe industry is planned by one ministry, the clothing industry by a second ministry, the steel industry by a third ministry, and so on, there is nothing to prevent all of these industries from drafting mutually contradictory plans. There is nothing to prevent them from basing their plans on the availability of the same labor, or the same material, fuel, transport facilities, or whatever. In such a case, to whatever extent one industry succeeds in obtaining the factors of production necessary to execute its plan, it simultaneously wrecks the plans of other industries.

Observe what is involved here. Because planning under socialism is necessarily both decentralized and lacks coordination, the production of each of the various goods can be expanded more or less randomly at the expense of destroying the production of other, more important goods. *This is exactly the same chaos that prevails under universal price controls and universal shortages.*

Furthermore, to whatever extent individual industries or factories are given discretion in the plans, the products that are produced can very well be unsuited to the needs of other industries that depend on them, and in that way wreck the plans of these other industries. For example, the plan for agriculture can be wrecked by the poor quality of tractors that break down too often or aren't suited for the terrain. Under socialism, suppliers do not have any incentive of profit and loss in meeting the requirements of their customers. Nor are they subject to any form of competition. Each branch of industry under socialism is a protected legal monopoly that is totally disinterested in the requirements of its customers. This, too, is exactly the same situation we observed in the case of price controls and shortages. And it applies, as I say, not only at the consumer level, but at the producer level as well.

Under socialism, each industry, as well as each consumer, is at the mercy of disinterested monopoly suppliers. To understand what this is like, first recall our discussion of the problems at service stations and in the relations between tenants and landlords resulting from price controls on gasoline and from rent controls.⁷ Now observe that similar or even worse problems exist around us in the present-day United States in practically every case in which the government is the supplier. For example, think of the services provided by municipal bus lines and subway systems, the public schools, the motor vehicle bureau, and the Post Office. All of these operations are notorious in the utter indifference and contempt they

display toward customers and in the low quality and lack of dependability of their services. These characteristics are the result of the fact that these operations are government owned and therefore operate without the incentives of profit and loss; in addition, they are generally immune from the threat of competition. Because of the lack of profit and loss incentives, it doesn't matter to them whether they gain customers or lose customers—whether they perform fast and efficient service or slow and inadequate service.

Now imagine the steel industry being owned by the government and run in the same way, and the customers of the steel industry having to contend with its performance. The industries needing steel would not be able to make their plans with very great confidence.⁸ Moreover, since they too would be owned by the government, they would not particularly *care* about not receiving the quality and service or even the kind of products they were supposed to. The effects on *their* customers, in turn, and on the plans of their customers, would be compounded.

For example, an industry waiting for a new factory, say, called for by its plan, would have to contend with the indifference and bad service of a construction industry suffering from the indifference and bad service of the steel industry. And so it would go, with the plans of each industry wrecked by the lack of incentives and poor performance of every other industry further back in the chain of supply. It is for these very reasons, which are tantamount to the conditions of chronic shortages, that suppliers in the Soviet Union were so unreliable that, as previously pointed out, each factory there strove as far as possible to be self-sufficient and thus independent of suppliers.⁹

To think of socialism as a “planned economy” is absurd. It is, in fact, an “anarchy of production”—a true anarchy of production.

The Soviet Quota System

The fact that socialism is an anarchy of production could not be better illustrated than by the famous Soviet “quota system.” Socialist planning in Soviet Russia assigned to each farm and factory a specified physical production goal, called its “quota”—for example, so many bushels of wheat or so many pounds of nails. And each farm or factory was encouraged *to exceed its quota.*

Now this situation is identical to the one we discussed under a system of universal price controls and universal shortages, for it means that there is a ready and waiting employment for more factors of production in every branch of production, with the result that any branch is capable of expanding at the expense of any other, more important branch. This, of course, is a system of pure chaos. The Soviet quota system, moreover, illustrated the

anarchy of socialist production in another major respect as well. The central planning authority did not even attempt to issue really precise production quotas because of the enormous additional detail that would have been required. For example, at times it did not even attempt to specify the number of each particular size nail or screw and so forth that was to be produced. It simply ordered the production of so many pounds or mere units of nails or screws or whatever, overall. As a result, depending on whether the orders were in terms of weight or mere number of units, the factories concerned were led to try to concentrate on items that were giant sized and enormously heavy, or pin sized and very large in number. For these were the ways most easily to meet and exceed the quotas. The disastrous results for subsequent production can be imagined.

The quota system and its stress on meeting and exceeding quotas is an inevitable consequence of the fact that socialism cannot rationally plan. It results from the fact that a socialist government wants to expand production, but is unable to trace the connections among the different industries. It is unable to determine—and is not even aware that it is necessary to determine—the effects of producing more of any one item on the ability to produce other items. A socialist government sees the particular product it wants to produce in each case, but, because it lacks a price system, it has no concept of the cost of producing that product or, therefore, of what other products it must forgo in the process. As a result, it simply gives orders to produce as much as possible of everything.

Socialism is simply unable to determine costs and is not concerned with costs. It should be realized how much more profound this lack of concern with costs is in a socialist economy than in the case of isolated socialized enterprises operating in an economy that is based on private ownership of the means of production. Today, for example, the Post Office is not overly concerned with costs, because there is no one in the Post Office who stands to make a profit by reducing costs or suffer a loss by allowing them to run up. In the context of a socialist economy, the problems of the Post Office, or any other enterprise, would be far more profound. In that case, it could not even know what its costs were, because of the absence of a price system. As a result, the Post Office, and every other enterprise under socialism, would be operated totally in the dark, with an unknown impact on the rest of the economic system.¹⁰

Shortages of Labor and Consumers' Goods Under Socialism

Because this will be an important matter for consideration in Part B of this chapter, it should be realized that

socialism's inability to determine costs and consequent lack of concern with costs produces exactly the same kind of *labor shortage* as exists under universal price controls. A labor shortage exists under socialism both because of a socialist government's desire to produce more of everything and because of its inefficiency in how it produces anything in particular. The latter circumstance increases the amount of labor required to produce each good. In addition, of course, shortages of consumers' goods contribute to the labor shortage. The extent of the labor shortage is such that factory managers routinely hoard labor, that is, keep it on the payroll, in idleness, merely to have it available as and when the need for it may arise.¹¹

A few words must be said specifically about the reasons for the existence of shortages of consumers' goods under socialism, especially since it is often claimed by socialists who have some familiarity with economics that such shortages could be avoided by a socialist society. Shortages of consumers' goods exist under socialism even without inflation. They exist as a result of the following factors. First, the chaos in the production and geographical distribution of the various goods: at any time, goods can cease being produced, or cease being sent to particular localities. This can occur because particular plans are fulfilled that snatch away the necessary factors of production or perhaps the very consumers' goods themselves from other plans. Second, when this happens, the managers of the local stores and warehouses of the socialist society have no incentive and no authority to raise prices. Nor do they have the incentive or authority to try to anticipate such events and build up stockpiles—that would be speculation. In the same way, they have no incentive or authority to bring in supplies from other areas (or send supplies to other areas)—that would be another form of activity possible only under capitalism, namely, arbitrage. In addition, all of the moral and political pressures of a socialist society work against prices being raised.

A basic moral postulate of socialism is that goods should be free to whoever needs them, or, if not free, then at least as inexpensive as possible. The political pressures of socialism are likewise overwhelmingly against price increases (a fact that in the Poland of the 1970s and 1980s was repeatedly confirmed by rioting and even by changes in the top officials on occasions when price increases were imposed). The reasons for such political pressures are exactly the same as those which make rent control so popular in New York City, namely, whoever succeeds in buying at the low price sees his benefit and applauds the government officials responsible; on the other hand, those who are victimized by the shortage the too-low price creates rarely see any connection between the

too-low price and their inability to obtain the goods they want; they view the low price as being in their interest, too, and hope to be able to buy at that price.

All of these circumstances create shortages of consumers' goods under socialism, which, of course, are worsened by the desire to hoard that necessarily accompanies them. On top of all this, the socialist government can issue additional money to the consumers and typically does so, which, of course, further intensifies the shortages by expanding aggregate demand in the face of a given level of prices.

4. Further Economic Flaws of Socialism: Monopoly, Stagnation, Exploitation, Progressive Impoverishment

The most fundamental fact about socialism is that *government ownership of the means of production constitutes an attempt to make intelligence and initiative in production a monopoly of the state.*

Production depends on the possession of means of production. If the means of production are monopolized by the state, because it arbitrarily claims to own them all, then no one is free to produce on his own initiative and to regard his own intelligence and judgment as the ultimate authority for his action. In a socialist economy, no one can produce without the permission, indeed, without the orders, of the state.

This attempted monopoly of intelligence and initiative is the cause of socialism's anarchy of production. Socialism simply *prohibits* all of the independent planning of millions of free, self-interested individuals that is required to run an economic system in a rational and ordered way.

There are additional, corollary consequences of socialism's monopoly character that must be stressed, namely, *the necessary technological backwardness of socialism and the utter powerlessness of the plain citizen under socialism.*

To understand these points, compare the conditions of socialism with those of capitalism. Under capitalism, whoever sees a profitable opportunity for action is free to act on his own initiative. He is powerfully motivated to do so by the prospect of the profit he can make. At the same time, he is restrained from rash action by the risk of losing his own money. In addition, his action constitutes a challenge to the established ways of doing things. For if what he is doing is in fact an improvement over present products or methods of production, then those producing the present products or practicing the present methods must copy him or be driven out of business. And, as we have seen, competition is powerfully promoted by the fact that if an innovator lacks capital of his own, he can turn to any one of hundreds or even thousands of

independent sources of financing by offering to share his profits with potential backers. Thus, under capitalism, every new idea has an enormous number of possible chances for being implemented.¹²

Because of its freedom of initiative, its incentives to use that initiative, and its freedom of competition, the products and methods of production of capitalism tend to be literally the very best that anyone in the entire society can think of, and to improve further as soon as anyone can think of any still better idea. We saw all this, of course, back in Chapter 6.¹³

Under socialism, on the other hand, individual initiative is paralyzed by the fear of punishment. Prison replaces profit for the man who would seek to implement an idea on his own initiative, for it is against the law under socialism to act outside the government's "plan." If an individual does manage to think of some improvement under socialism, he must submit it to the government. If he does so, he will at most have only a handful of chances for approval of his idea. In addition, whatever officials he turns to in the government will have no economic incentives to adopt his idea, whatever its possible merit. They will be inclined to reject it, in order to spare themselves the difficulties and uncertainties that are always entailed in implementing an innovation—such as the need to find new suppliers of raw materials, obtain new workers, or discharge or relocate present workers. The officials will not want to run the risk of the innovation being judged a failure and thus arousing the displeasure of those in a position to do them harm. At the same time, if the innovation were somehow to succeed, by whatever arbitrary standard success is judged under socialism, the effect on the officials would likely be merely the difficulties of establishing the new arrangements and then having their assigned production quotas increased. These are the conditions that prevailed in the former Soviet Union.¹⁴ Under such circumstances, very few new ideas are thought of, fewer still are implemented, and virtually none at all are of benefit to the plain citizen.

The complete and utter powerlessness of the plain citizen under socialism can hardly be exaggerated. Under socialism, the plain citizen is no longer the customer, "who is always right," but the serf, who must take his rations and like it. For no official of a socialist government stands to make a profit by supplying him better or suffer a loss by supplying him worse. These officials both lack the incentive of profit and loss and need not fear any competition from the initiative of outsiders. Thus, the plain citizen is economically powerless against them.

It is not even necessary to speak of the absence of any improvements for the plain citizen. Even if it had the ability, socialism has *no reason* to supply the plain citizen even with such goods as already exist and to which he

may have grown accustomed in the preceding era of capitalism. Indeed, it has no reason to supply him with *anything more than is necessary to prevent an uprising*. Consider a simple example. Assume there is a neighborhood somewhere that needs a grocery store. Under capitalism, this need represents a profitable opportunity for someone. Whoever sees it and has no better opportunity available simply opens a grocery and proceeds to make money, at the same time satisfying the neighborhood's need.

Under socialism, on the other hand, the residents of the neighborhood can obtain a grocery only by petitioning the economic planning board for one. Even if the residents actually went so far, which is itself highly doubtful, the officials of the board would have no compelling reason—no personal material incentive—to comply with their request. They would certainly be far less likely to do so than officials in the United States who presently accede to requests for traffic lights at dangerous intersections, which is often only after repeated deaths have occurred. It is for these very reasons, incidentally, that even Moscow, the leading city of socialism, is grossly lacking in retail and service establishments; residents living in outlying suburbs must often travel all the way to the center of the city to obtain even such things as food supplies.¹⁵

To take a second example: if ten million citizens of a socialist state are without shoes and must go barefoot, this does not and cannot mean any more to the officials of the socialist state than it means to the officials of New York City that everyday hundreds of thousands of New Yorkers are subjected to inhuman, cattle-like conditions in the city's municipalized subway system. No government official is motivated seriously to work to do anything about such conditions, because he has no profit/loss incentive to improve them. He will not grow richer by improving them. He will not grow poorer by leaving them alone.

The closest a government official could come to having an incentive to make an improvement anywhere is if he were running for election and the outcome of the election depended on that improvement. Then, until the clamor died down, he might attempt to do something to make that particular improvement—at the expense, of course, of sacrificing other areas, where fewer complaints would be generated. Such an occasional, narrow political incentive, however, is as nothing compared with capitalism's freedom of individual initiative motivated by the incentives of profit and loss. This immensely powerful combination of freedom and incentive under capitalism is continually applied to improving all aspects of economic life, the overwhelming majority of which can never even be the subject of an election. For example,

that specific neighborhood's getting a grocery store cannot be the focus of a mayoral election, much less a national election. It would simply be lost in the shuffle of far too many other matters. The same is usually true even of such larger matters as ten million people going barefoot or hundreds of thousands being treated like cattle. These are likely merely to have the status of particular dissatisfactions among innumerable other dissatisfactions and thus require no special urgency of response on the part of government officials.

Furthermore, under socialism, for reasons to be explained in Part B of this chapter, there are no free elections, and thus even the occasional democratic political incentive does not arise. Under socialism, the closest a government official comes to having an incentive to improve conditions is when the populace is on the point of revolt and it is more expedient to make some show of improvement rather than crush the protest with force.

In contrast to the politicians, democratic or totalitarian, the people who really do work to improve the economic conditions of the general public, who—literally—stay up nights thinking of ways to provide them with such things as grocery stores, more and better shoes and means of transportation, and everything else they may possibly want, are *capitalists*, who are continually motivated by the prospect of making or losing a fortune and who can act on their own initiative. Capitalists know not only that they will profit from improving conditions but also that if they fail to make improvements, others can make them and that the resulting competition will cause those who have not made the improvements to lose the wealth they now own.

The simple fact is that under socialism, the consumers must accept whatever the government decides to give them, however meager and inadequate that may be. For the rest, they are helpless, and whatever pleas they might make fall on deaf, indifferent, and often hostile ears.

The paralysis of initiative and incentives under socialism knows no limit—it extends to death itself. For example, if one asks how it is that Russia under socialism could periodically be threatened by famine despite the fact that it possessed the world's richest farm land, in the Ukraine, and was a major wheat exporter even under the Czars, the answer is that the individual Russians were prevented—by physical force—from taking the actions necessary to save their lives. Russian peasants, however ignorant they may have been, were not so ignorant that they did not know that to eat they must grow food; nor did they lack the knowledge to grow sufficient food. They could have grown not only enough to feed themselves, but the urban population of the country as well, and far more. The urban population could have produced things of value to the peasants, and they could mutually

have exchanged and both have lived far removed from the threat of starvation.

The reason they did not is quite simple: The Soviet government arbitrarily declared the whole of the Soviet Union to be its property, and refused to allow the peasants to farm for their own profit or the urban population to produce for its own profit. It threatened, quite literally, to kill anyone who tried to do so. Thus, a Russian peasant may have looked at virgin forest land that he could have cleared and made his farm, and which would have fed himself and ten others. He may have looked, but he would not have lifted a finger, because he would have been killed for trying. People starve to death under socialism because the actions they would have to take to prevent starvation would bring them a more immediate death from the government. It is that simple.

It follows from the powerlessness of the plain citizens that *the government of a socialist country is not and has no reason to be interested in anyone's values but those of its rulers*. This principle applies both to technological developments and to the whole of production. The only kind of technological developments that a socialist government is interested in are those which are of value to its rulers: above all, improvements in weapons production and in the kinds of things that add to the rulers' prestige, such as "sputniks"—or pyramids. Of course, even these, or their base, it must steal from capitalist countries, because it is impossible significantly to develop military technology, or any other aspects of technology of special interest to the state, while repressing civilian technology. For example, the tank and the military airplane could not have been developed in the absence of the automobile. Radar and rocketry could not have been developed in the absence of radio. But the automobile and radio would never have been introduced under socialism. They could not because the motive that inspires the introduction of such goods is pleasure and profit—the personal, selfish pleasure of the consumers and the private profit of the producers—not collectivistic duty and altruistic sacrifice.¹⁶

The only kind of production a socialist government is interested in is the production of weapons, spectacles, and monuments, which enhance the power and prestige of the rulers—and of just enough consumers' goods to prevent mass starvation or, perhaps, a revolt, either of which would weaken its power. Ironically, in *Das Kapital*, Karl Marx refers to capitalists as "blood-sucking," "vampire-like" "exploiters." It is clear, however, that it is not capitalists, but the rulers of socialism who are the genuine "blood-sucking," "vampire-like" "exploiters" of labor. Minimum physical subsistence is the most they will ever voluntarily give to the masses, for they have absolutely no reason to give more. Over seventy years of

communism in the Soviet Union served to confirm this principle. But in the long run they cannot even provide this much. For, as should be apparent, as a result of its "anarchy of production," socialism "cannot even maintain its slaves in their slavery": the workers of socialism "sink deeper and deeper into poverty"—to borrow some other of Marx's choice clichés and apply them truthfully for once.

If anyone doubts that the standard of living under socialism tends to sink below the level of minimum physical subsistence, let him consider where the citizens of the former Soviet Union would be right now without American wheat. Let him consider how many of them would die from the famine that would then result. Let him consider how many of them would already have died from the numerous famines that have been averted only because of the existence of an outside capitalist world to turn to for grain supplies. The citizens of the former Soviet Union averted famines and countless other disasters only because an outside capitalist world existed to provide them with all sorts of supplies to make good the errors of their chaotic economy. Their system was able to drag itself out for over seventy years only by means of the direct or indirect aid of the United States and other Western governments, which was responsible even for most of their ability to export and thus to pay for some of their imports.¹⁷

As previously stated, without the aid of capitalist countries, socialism must revert to feudalism, for it could not feed an extensive urban population. Such urban population as it might begin with would be destroyed by famines or flee to the countryside to avoid such destruction. These results must ultimately occur even if socialism were to begin with the present economy of the United States, the inheritance of more than two centuries of capitalism. For the chaos of socialism would so reduce production as to make it impossible to replace the existing stock of capital goods. Then, as a result of fewer capital goods, production would drop again, and the supply of capital goods would thus decline still further. Socialism would find itself caught in the vicious circle I described in the last chapter, of less production causing fewer capital goods causing less production.¹⁸ The day would come when, no matter how high the level at which it began, it could not feed the population. Socialism is an utterly destructive and self-destructive economic system.

The overwhelming inefficiencies of socialism shed light on what otherwise might be a puzzling phenomenon, namely, the inability of the former Soviet Union, despite its alleged concentration on the production of capital goods for most of its history, significantly to increase its per capita production of consumers' goods,

or, indeed, to accumulate any very great amount of additional capital goods. If the apologists for the Soviet Union were to be believed, the reason for its miserably low production of consumers' goods was its concentration on the production of capital goods—on the “building up of heavy industry.” Now it would be possible, perhaps, to explain the lack of consumers' goods for a few years on the grounds that the means for producing them have been devoted to the production of capital goods, instead. If, however, capital goods have in fact been accumulated, the effect is to make possible an increase in the production both of capital goods *and* consumers' goods, because the possession of more capital goods raises the overall ability of an economic system to produce.

If, with a greater overall ability to produce, an economic system still does not produce more consumers' goods, the explanation cannot be that it is continuing to devote some given high proportion of its efforts to the production of capital goods. If the production of capital goods is to be the explanation at all, it must be that the economic system devotes *a larger and larger proportion* of its growing ability to produce to the production of capital goods. In the case of Soviet Russia, which had had little or no increase in the average standard of living since 1913 (indeed, as we have seen, would have suffered from famines in the absence of an outside capitalist world to turn to), this would imply that by the 1970s or 1980s, something on the order of ninety-nine and forty-four one-hundredths percent of its output must have been in the form of capital goods, and be increasing further every year—that by then Soviet Russia must have been purer in its devotion to the production of capital goods than Ivory is in soap; that it must have been one enormous factory from Leningrad to Vladivostok.

Yet, curiously, with all this implied devotion to the production of capital goods, the Soviet Union could not generate sufficient capital of its own to build an automobile or truck factory or natural gas pipeline. Again and again, it had to turn to the United States, to Japan, and to Western Europe—even to Italy, which was the source of its most important automobile factory.

The truth is, a socialist country can never accumulate much capital, even under the most favorable circumstances of outside aid, because its inefficiencies are so great. The greatest efforts it devotes to the production of capital goods are always in danger of being more than offset by the *low productivity of those efforts*, to the point that it cannot even replace the capital goods it consumes in production, and thus must decumulate capital. The former Soviet Union, and every socialist country, was in the position of a farmer who is so inefficient that for

every bushel of seed he uses up in production, he can barely produce a bushel of crop. With such inefficiency, no matter how great the concentration on the production of capital goods, very little indeed can remain after allowing for the minimum subsistence of the producers as well as the replacement of the capital goods consumed in production.

Capital accumulation under socialism is possible only at the cost of human life, on the scale imposed by Stalin. Stalin ordered the production of capital goods at the expense of the production of the food and clothing and other necessities required to sustain the lives of the producers. To build hydroelectric stations, steel mills, and armaments factories, he consumed the lives of tens of millions of human beings. These are facts which Gorbachev should have kept in mind when he simultaneously condemned Stalin for being a tyrant and credited him for the development of the Soviet economy. *Under socialism, economic development is possible only under the kind of tyranny and mass murder practiced by Stalin.* It is the exchange of human lives for piles of steel and concrete, which in turn, as the source of weapons for military aggression to further extend the power of socialism's rulers, are useful only for further destruction. When the mass murder lets up, the result is “the years of stagnation” for which Gorbachev denounced the Brezhnev era.

Of course, when left entirely to its own inefficiencies, without an outside capitalist world to turn to, socialism cannot maintain either the capital it inherits from capitalism or what it has accumulated through mass murder. Its inefficiencies are then so great, its production so limited in comparison with the capital goods being used up, wearing out, or deteriorating with age, that with or without mass murder it decumulates capital and retrogresses—to the economic conditions of feudalism and the Dark Ages.

In such circumstances, the economic self-destructiveness of socialism would not be reduced even if a socialist society abandoned its quest for war-making power and thus did not maintain a large-scale military establishment. Its economic self-destructiveness rests on the fundamental chaos and inefficiencies of the system. Socialism can accomplish nothing, including the maintenance of a significant military establishment, without the support of an outside, capitalist world, which continuously provides it with vital supplies. In the absence of the maintenance of a military establishment, its chaos and inefficiencies would render it no less dependent on an outside, capitalist world. Thus, in the absence of the necessary support from the capitalist world, socialism must collapse with or without the maintenance of a military establishment.

5. Socialism's Last Gasp: The Attempt to Establish a Socialist Price System and Why It Is Impossible

Von Mises's demonstration of the chaotic consequences of socialism's lack of a price system has not gone entirely unnoticed. While practically all socialists continue to denounce the "wages system" and to extol what they call "production for use" above the hated "production for profit," a handful of academic socialists who are conversant with economics have recognized the devastating power of von Mises's criticisms.

According to these socialists, it was a minor oversight of all other socialists to have failed to understand the operations of the price system and to have sought to destroy it, and thus to destroy all of civilization along with it, for over a century. Fortunately, however, before socialism could destroy civilization, the material productive forces have come to the rescue and made von Mises see the problem, and his criticisms have now led this handful of academic socialists to recognize what must be done to avert disaster. I do not exaggerate. Oskar Lange, formerly of the University of California and the University of Chicago and later deputy premier of Communist Poland, wrote:

Socialists have certainly good reason to be grateful to Professor Mises, the great *advocatus diaboli* of their cause. For it was his powerful challenge that forced the socialists to recognize the importance of an adequate system of economic accounting to guide the allocation of resources in a socialist economy. Even more, it was chiefly due to Professor Mises's challenge that many socialists became aware of the very existence of such a problem. . . . a statue of Professor Mises ought to occupy an honorable place in the great hall of the Ministry of Socialization or of the Central Planning Board of the socialist state. . . . a socialist teacher might invite his students in a class on dialectical materialism to go and look at the statue, in order to exemplify the Hegelian *List der Vernunft* [cunning of 'reason'] which made even the stanchest of bourgeois economists unwittingly serve the proletarian cause.¹⁹

The alleged solution to the economic problems of socialism offered by Lange and the others (whom we must view as a kind of self-styled vanguard of the vanguard of the proletariat, trying to teach the vanguard not to act as a barbarian horde) is known as "liberal socialism" or, sometimes, "market socialism." It consists in the construction of a mythical economic system that is analogous to the centaur of Greek mythology, the beast that was supposed to be half man, half horse. That system is *capitalism's price system appended to the body of socialism*. Socialism is to have free-market prices for all goods and services. It is to have wages, interest, and profits. The hated "wages system," that Marx spent his life attacking, is to be retained. Production is to be "production for

profit," not, as all socialists have always said previously, "production for use." In this way, socialism is allegedly to be able to have all the advantages of capitalism, plus more; for it will simultaneously pocket all of the profits that under capitalism would go to the capitalists. Profits will serve as a "parameter," that is, as a guide to what to do—though, of course, no one will actually profit from doing what he is supposed to do.

This doctrine, incidentally, was presented for consideration in Soviet Russia under Khrushchev. It was known as "Libermanism," after a Russian professor of that name. The proposed role of profits was described with great fanfare at the time, in practically the very words I have used. "Libermanism" has not been heard from since, and with good reason, as we shall see.

Now the way socialism is to achieve a price system is by dividing the socialist economy up into separate sections or firms. Each will be assigned a balance at the government's central bank. The government will set prices for all goods and services. At least on paper, these firms will then buy from and sell to each other; they will also sell to consumers and pay wages. They will pay interest on capital to the government's central bank and even to other enterprises, and they will record profits and losses.

There is really nothing astonishing in any of this. It is similar to socialism on the German or Nazi pattern, in that seemingly separate, independent enterprises will exist. Lange, Liberman, and the others simply want to convert Russian-style socialism into something more closely resembling German-style socialism.

They go further. They claim that many or most of the controls of German-style socialism can be abolished. They claim that a price system can be developed within the context of their German-style socialism, that would make it unnecessary for the government to engage in specific allocations of physical factors of production. They claim, in effect, that all the government need do is allocate capital in money terms to different enterprises or individuals, tell them to invest and produce in the lowest-cost, most profitable way, and then everything will take place as under capitalism except that the government will rake in the profits. There allegedly need be no problem of shortages as a result of the government's prices being set too low, or unsalable surpluses as a result of its prices being set too high; for as soon as such shortages or surpluses appear, it is claimed, the government can raise or lower the prices concerned and thus achieve a balance between supply and demand.

Now the absurdity of what Lange, Liberman, and the others propose can be grasped most simply by starting with the existence of capitalism and then imagining two alternative things to occur: (1) the government imposes

price and wage controls, (2) the government obtains the power to expropriate any firm's or individual's capital and turn it over to any other firm or individual at its discretion. After we look at the consequences of each of these measures separately, we can consider their operation in conjunction; and that will describe what to expect from any attempt at a "price system" under socialism.

According to Lange, Liberman, et al., a socialist government could have a price system and make it work by varying prices in response to changing conditions of supply, demand, and cost. In the case of price controls imposed on an existing capitalist system, the individual capitalists have a powerful personal incentive to try to push the government to change its controls every time there is a change in supply, demand, or cost. It is absurd to believe, however, that the government could be made to change its controls in the same way that the capitalists would have changed their prices in a free market.

To make this as concrete as possible, what Lange, Liberman, and the others are implying—though apparently without being aware of it—is that the government could control the price of oil and gasoline and apartment rents and so forth, and would then vary its controls every day in just the same way as a free market would have varied its prices. Now if this were really so, we must ask why the U.S. government did not listen to the oil companies and raise the controlled price of oil and gasoline during the oil shortages of 1973 and 1979, or why the New York City rent-control authorities have never listened to the landlords and raised the controlled rents in the face of the shortage of rent-controlled housing? We must ask why price controls are imposed in the first place, for what purpose could they serve if they were really to duplicate the prices charged in a free market?

The fact is that government price-control officials do not and cannot control prices in the way a free market would have set them. For the basis of the free market's prices is the *self-interests* of the different individuals concerned, acting in an environment of freedom of competition. A gas station owner, an oil company, a landlord, and so on, sets his price on the basis of what is most profitable *for him*, given the same endeavor of all others in setting their prices and in choosing whether or not to pay his. *Self-interest, operating under the freedom of competition, is the driving force of price determination under capitalism. Government control of prices thwarts this driving force.*

While price controls thwart this driving force, the socialization of the economic system destroys it utterly, and more besides.

There is one, indispensable control that socialism must have, even under the most relaxed imaginable variant of the German-style socialism envisioned by

Lange, Liberman, et al.; and that is *the right to withdraw capital at any time from any enterprise and make it available to any other enterprise*. This minimum control on the allocation of capital is inescapably implied in the very nature of government ownership: if the government is to be the owner, the enterprises and those in charge of them can have no right to regard the capital at their disposal as theirs for one moment longer than the government wishes it.

To grasp the significance of this fact, let us forget about price controls for the moment. Let us return to an existing capitalist system, and assume that all the government does is obtain the power to expropriate the capital of any firm or individual and turn it over to any other firm or individual at its discretion. This is the equivalent to what it must be able to do, as a minimum, under the most "liberal" variant of so-called market socialism. Thus, for example, one year, it uses this power to halve or totally eliminate the capital of the General Motors Corporation and build up the capital of other enterprises. The next year, it gives the real estate of Manhattan Island to a different group of owners. In the following year, it dispossesses the farmers of New Jersey and turns their farms over to others. The government can do this in the same way that a private business today can close down some branches and open others, or fire existing managers and replace them with new ones—for the property is the government's, not that of the private firms or individuals any longer.

Now this measure would totally destroy all the incentives of ownership.

Nevertheless, it is to people in such a position that "market socialism" in its logically consistent form wants to entrust the supreme management of the socialist economic system. "Market socialism" wants the socialist government to place capital in the hands of firms and individuals who will have absolutely no incentives of ownership, and then to give them discretion as to its investment. It wants the government to delegate its responsibility for investment to them, by giving them capital and then telling them to go and make believe they are capitalists. As I have said, it expects that then everything will work as under capitalism except that the state will be able to claim all of the profits.

If this system were actually implemented, those to whom the socialist state entrusted the use of its capital at any time would be in the position of owners of capital at the pleasure of the state. Their powers of discretion in investment would be genuine powers of ownership, but they would last no longer than the state desired. They would be in the position of people facing the constant threat of expropriation. They would, in effect, be prop-

erty owners, but they would be less secure in their possession of property than were the owners of fields along the coast of Europe in the era of the Viking raids. It is obvious that the self-interest of people in such a position is very different from that of capitalists under capitalism. Not being secure owners of property, they are not in a position to think of enhancing its value on a long-range basis. Their horizon extends no further than the immediate moment. If they are given significant discretion in its use, their self-interest lies with personally consuming as much of the capital entrusted to them as possible, or converting it to some concealable form, such as gold or jewels. If the socialist state effectively thwarts this motive, it succeeds merely in securing the services of people who are disinterested in the most literal sense of the term.

To grasp the nature of this disinterest, simply think again of our example of the General Motors Corporation, the owners of Manhattan real estate, the New Jersey farmers, and so on. Under “market socialism,” all of them have the threat of impending expropriation hanging over their heads. Their self-interest is to consume or conceal as much of their property as possible. We may assume that to prevent this, the government issues orders severely punishing such acts, and that it thereby actually succeeds in stopping them. Now what? Now, the “market socialists” believe, these property owners will be willing to simply go to work for the state with the same zeal with which they would have worked for themselves, and will continue in loyal service until the day the state expropriates them and turns their property over to a new set of owners. Then this new set will do the same thing.

It should be clear that what all of the abstruse talk of the “market socialists” about the “parametric” function of profits in a socialist society boils down to is this: It is profitable to a man to clear and cultivate a field, to develop a business, to construct a factory, which is why under capitalism he does it. Under socialism he will allegedly still do it, not because it is profitable *to him*, but because it is “parametrically” profitable—that is, profitable *to his expropriators*. If traditional socialism requires that an omniscient deity assume command of the socialist economy to make it work, “market socialism” requires the descent of Jesus of Nazareth, Francis of Assisi, and all the other saints of altruism, who will, in the meantime, assume the garb of hard-nosed, calculating businessmen. “Market socialism” is the same old line of “from each according to his ability, to each according to his need,” but dressed up in the ludicrous guise of the businessman’s quest for profit.

I have not mentioned the opportunities for corruption that a system of “market socialism” would create, nor,

having now mentioned them, will I dwell on them. It is clear, however, that under such a system vast personal fortunes could rotate, as it were, among succeeding sets of government favorites who were awarded the right to invest the capital of the economic system.

It is really a nonessential under “market socialism” whether the government explicitly controls prices or not. It could delegate this responsibility to the individual enterprises if it wished. If it did, it might achieve an economic system at the level of, say, Turkey under the arbitrary, despotic rule of the sultans, when no one could be secure in the possession of any property—when no one dared to improve his house or fields, let alone build a factory, for fear of having them seized by the government.

If the government does control prices, as Lange and the others actually suggest, it is absurd to believe that the enterprises to whom it entrusts capital will be zealously besieging the price-control office with requests to raise or lower them so as to balance demand and supply; or, of course, that the price-control office would have any more reason to listen to their requests than when price controls are imposed on an existing capitalist system.

It is obvious that socialism cannot rationally entrust its management to people who either have no incentive at all or an incentive to grab what they can while the opportunity exists. And, in fact, none of the so-called market socialists is actually consistent enough to go very far in his proposals. Without ever explicitly mentioning it, and certainly without ever stressing the fact, they all take for granted that the state will give precise orders to each enterprise concerning what industry or industries it is to operate in, what products it is to produce, how many factories it is to have, and where, and what kind and how many machines it is to have. The discretion they are actually willing to allow is in the relatively minor and very narrow area of how best to use the existing quantity and quality of plant and equipment assigned, for the purposes assigned.

But this brings “market socialism” back to all of the problems of socialist “planning” that it claims to have solved. For in this case, the state must still decide the relative size of the various industries, the quantity and composition of their output, their basic methods of production, and their physical location. And, as we have seen, it has no rational way of deciding these things, for it must attempt to plan the totality of the economic system as an indivisible whole while being simply incapable of comprehending the specific details of the economic system and their myriad interrelationships.

The limited discretion the “market socialists” want to

allow would only introduce further disruption into the already anarchic conditions of socialist production. For it would allow enterprises on their own initiative to snatch away materials, supplies, and labor from other enterprises in ways that could not be controlled by the government planners, and which would thus disrupt even such limited, partial planning as they are able to accomplish on behalf of projects of special priority. Imagine, for example, the government of Soviet Russia trying to build a tank factory, only to find that it could not do so because some of its own enterprises had snapped up all the supplies of some vital material or part. It is for this very reason, I am sure, that “market socialism”—even of the very timid variety actually recommended by Lange and the others—was never tried in any socialist country, is unlikely ever to be tried, and, if tried, would soon be abandoned.

The only solution for the problems of socialism is, as von Mises saw over seventy years ago, the restoration of capitalism.

Indeed, the debate over market socialism is now closed and the correctness of von Mises’s position definitively established. It is established by the recognition on the part of socialist regimes all across the world that it is necessary to establish private ownership of the means of production. It is established by the overwhelming fact that all across the world the cry is raised “no more socialism” and efforts are underway in almost every socialist country to establish capitalism.

In echo of these momentous developments, it is gratifying to read the words of a lifelong socialist and admirer of the Soviet Union, Robert Heilbroner, who now says, “Fifty years ago, it was felt that Lange had decisively won the argument for socialist planning. . . . It turns out, of course, that Mises was right. . . . From what we know now [which von Mises knew in 1922] about how anarchic the planning process was, the wonder is not that the Soviet economy has given out but that it went on as long as it did.”²⁰ Heilbroner also declares: “At a recent meeting near Washington, Soviet economists from the prestigious Academy of Sciences disputed the ‘pessimistic’ conclusions of the C.I.A. that the Soviet G.N.P. was today only between one-half and one-third as high as that of the United States, and that Soviet citizens enjoyed the equivalent of Portuguese or Greek living standards. The Soviet experts maintained that a truer measure put the Soviet G.N.P. at one-seventh of the American—a figure that yields a per-capita standard of living in the Soviet Union which is approximately that of China.”²¹

PART B

THE TYRANNY OF SOCIALISM

1. The Tyranny of Socialism

The chaos of socialism is equalled only by the tyranny of socialism. In abolishing economic freedom, socialism abolishes political freedom. In abolishing property rights, it abolishes civil rights. In a word, socialism means the establishment of a totalitarian dictatorship.

It must be stressed again that when I refer to socialism, I am referring to *all* variants of socialism—the socialism of the allegedly respectable socialists, such as the Social Democrats, as well as the socialism of the Nazis and Communists. I stress this fact because a widespread misconception prevails that somehow the “good” socialists could achieve socialism by peaceful means and thereafter preserve political freedoms and civil liberties. That is not so, and it has never been so. And no one should make the mistake of thinking that countries like Great Britain, Israel, and Sweden have been or are exceptions. As we have seen, these countries have not in fact been socialist countries, but “mixed economies.”²²

In every instance in which socialism has actually been enacted, as, for example, in Nazi Germany, Soviet Russia, Communist China, Communist Cuba, and all the other Communist-bloc countries, its totalitarianism has been manifest. It is only necessary to show why the violent, bloody means that have been employed to achieve socialism, and the perpetual reign of terror that follows thereafter, are no accident, but are caused by the very nature of socialism; why, in other words, socialism is a thoroughly evil end, necessitating evil means for its achievement, and necessarily producing the most evil consequences.

2. The Necessity of Evil Means to Achieve Socialism

Let us begin by considering the means employed to achieve socialism. We observe two phenomena that are not unrelated. First, wherever socialism has actually been enacted, as in the Communist-bloc countries and Nazi Germany, violent and bloody means have been used to achieve it and/or maintain it. And, second, where socialist parties have come to power but abstained from wholesale violence and bloodshed, as in Great Britain, Israel, and Sweden, they have *not* enacted socialism, but retained a so-called mixed economy, which they did not radically or fundamentally alter. Let us consider the reasons for these facts.

Even if a socialist government were democratically elected, its first act in office in implementing socialism

would have to be an act of enormous violence, namely, the forcible expropriation of the means of production. The democratic election of a socialist government would not change the fact that the seizure of property against the will of its owners is an act of force. A forcible expropriation of property based on a democratic vote is about as peaceful as a lynching based on a democratic vote. It is a cardinal violation of individual rights. The only way that socialism could truly come into existence by peaceful means would be if property owners *voluntarily donated their property to the socialist state*. But consider. If socialism had to wait for property owners to voluntarily donate their property to the state, it would almost certainly have to wait forever. If socialism is *ever* to exist, therefore, it can only come about by means of force—force applied on a massive scale, against all private property.

Further, in the case of the socialization of the entire economic system, as opposed to that of an isolated industry, no form of compensation to the property owners is possible. In the case of an isolated nationalization, the government can largely compensate the former owners by taxing the rest of the property owners to some extent. If the government seizes all property, however, and simply abolishes private ownership, then there is just no possibility of compensation. The government simply steals everyone's property lock, stock, and barrel. In these circumstances, property owners will almost certainly resist and try to defend their rights by force if necessary, as they properly should.

This explains why it takes the Communists to achieve socialism, and why the Social Democrats always fail to achieve socialism. The Communists, in effect, know that they are out to steal all of men's property from them and that if they expect to succeed, they had better come armed and prepared to kill the property owners, who will attempt to defend their rights. The Social Democrats, on the other hand, are held back by fear from taking the steps that would be necessary to achieve socialism.

In sum, the essential facts are these. Socialism must commence with an enormous act of theft. Those who seriously want to steal must be prepared to kill those whom they plan to rob. In effect, the Social Democrats are mere con men and pickpockets, who engage in empty talk about pulling the "big job"—socialism—someday, and who flee before the first sign of resistance by their intended victims. The Communists, on the other hand, are serious about pulling the "big job." They are armed robbers prepared to commit murder. This is why the Communists are able to implement socialism. Of the two, only the Communists are willing to employ the bloody means that are necessary to implement socialism.

3. The Necessity of Terror Under Socialism

If socialism is not to be achieved by open force, the only other way it can be achieved is behind people's backs—i.e., by fraud—which is the method of price and wage controls. This was the route chosen by the Nazis.

But however socialism may be achieved, whether by open force or by fraud, its maintenance requires a reign of terror. It requires an environment in which people cannot trust even their friends, an environment in which they are afraid to express any ideas of their own, or even to ask questions. It requires precisely the kind of environment that existed in Nazi Germany and is characteristic of every Communist country.

In order to begin to understand this point, let us consider merely the requirements of enforcing price and wage controls in an economy that is falling under the rule of de facto socialism. Let us imagine our own economy suffering from universal price controls and universal shortages and observe what would be required just to enforce the price-control regulations and prevent the development of a black market so large as to make the price controls largely meaningless.

Imagine, therefore, that we have a fully price-controlled economy, and that enough time has gone by to create shortages of practically everything. Imagine that we have gasoline shortages, meat shortages, power shortages, shoe shortages—shortages of all goods. In these conditions, every seller would have a powerful self-interest in charging higher prices than the law allowed, and every buyer would have a powerful self-interest in offering to pay such higher prices as a means of outbidding others, in order to obtain a larger supply for himself. How could the government stop the buyers and sellers from pursuing their mutual self-interests and transacting business above its ceiling prices?

Obviously, there would have to be penalties imposed for selling above the ceiling prices. But what kind of penalties? If a seller stood to make the equivalent of an extra twenty or thirty thousand dollars a year, say, by defying the price-control regulations, an occasional small fine would certainly not be a sufficient deterrent. And probably even the smallest neighborhood shops would stand to take in far more than that amount of extra income by defying the regulations. If the government were serious about its price controls, therefore, it would be necessary for it to impose severe penalties—penalties comparable to those for a major felony.

But the mere existence of such penalties would not be enough. The government would also have to make it actually dangerous to conduct black-market transactions. It would have to make people fear that in conducting such a transaction they might somehow be discovered by the

police, and actually end up in jail. In order to create such fear, the government would have to develop an army of spies and secret informers. For example, the government would have to make a storekeeper and his customer fearful that if they engaged in a black-market transaction, some other customer in the store would report them. Because of the privacy and secrecy in which many black-market transactions could be conducted, the government would have to make anyone contemplating a black-market transaction fearful that the other party might turn out to be a police agent trying to entrap him. The government would have to make people fearful of their long-time associates, even of their friends and relatives, lest even they turn out to be informers.

And, finally, in order to obtain convictions, the government would have to place the decision about innocence or guilt in the case of black-market transactions in the hands of an administrative tribunal. It could not rely on jury trials, because it would be unlikely that many juries could be found willing to bring in guilty verdicts in cases in which a man might have to go to jail for several years for the crime of selling a few pounds of meat or a pair of shoes above the ceiling price.

In sum, therefore, the requirements merely of enforcing price-control regulations would be the adoption of essential features of a totalitarian state, namely, the establishment of the category of "economic crimes," in which the peaceful pursuit of material self-interest is treated as a criminal offense, and the establishment of a totalitarian police apparatus replete with spies and informers and the power of arbitrary arrest and imprisonment. Clearly, the enforcement of price controls requires a government similar to that of Hitler's Germany or Stalin's Russia. If the government is unwilling to go to such lengths, then, to that extent, its price controls prove unenforceable and simply break down. The black market then assumes major proportions.

Now observe that in a socialized economy, a black market also exists. Only in this case, its existence entails the commission of further crimes. Under de facto socialism, the production and sale of goods in the black market entails the defiance of the government's regulations concerning production and distribution, as well as the defiance of its price controls. For example, the goods themselves that are sold in the black market are intended by the government to be distributed in accordance with its plan, and not in the black market. The factors of production used to produce those goods are likewise intended by the government to be used in accordance with its plan, and not for the purpose of supplying the black market. Under a system of de jure socialism, such as existed in Soviet Russia, all black-market activity necessarily entails the misappropriation of state property. From the point of

view of the legal code of a socialist state, most black-market activity must be regarded as theft of state property. For example, the factory workers or managers in Soviet Russia who turned out products that they sold in the black market were considered as stealing the raw materials supplied by the state.

Observe further. In a socialist state, the government's economic plan is part of the supreme law of the land. We have already seen in Part A of this chapter how chaotic the so-called planning process of socialism is. Its further disruption by workers and managers siphoning off materials and supplies to produce for the black market, is something which a socialist state is logically entitled to regard as an act of *sabotage*. And that is how the legal code of a socialist state does regard it. Consistent with this fact, black-market activity in a socialist country often carries the death penalty. In Nazi Germany, people were beheaded for it. In Soviet Russia, they were shot for it.

Even apart from possible indulgence in black-market activity, every socialist official who has responsibility for production necessarily leads a dangerous life. On the one hand, any use of factors of production in a way different than that specified by the state's economic plan lays such an official open to a charge of sabotage. On the other hand, it is generally impossible for the state's economic plan to be very precise, as we have seen; and so some discretion must be used. Since a socialist economic system functions in a state of continuous chaos and chronic crisis, it is very easy for any given official to be singled out and blamed for some disaster caused by socialism's anarchy of production. It becomes an essential talent under socialism for an official to be able to know how to cover himself and always to have scapegoats of his own at hand. From the top to the bottom, an incredible game of buck passing, favor trading, and mutual blackmail takes place. Ever-shifting alliances and factions are formed for mutual protection. And, periodically, victims are sacrificed: usually, subordinate officials here and there; sometimes, entire factions in giant purges.

The fundamental fact driving socialism to a reign of terror is the incredible dilemma in which the socialist state places itself in relation to the masses of its citizens.²³ On the one hand, the socialist state assumes full responsibility for the individual's economic well-being. It openly avows this responsibility—this is the whole source of socialism's popular appeal. On the other hand, in all of the ways I have shown, the socialist state makes *an unbelievable botch of the job*. It makes the individual's life a nightmare. Every day of his life, the citizen of a socialist state must spend time in endless waiting lines. For him, the problems Americans experienced in the gasoline shortages of the 1970s are normal; only he does not experience them in relation to gasoline—for he does

not own a car and has no hope of ever owning one—but in relation to simple items of clothing, to vegetables, even to bread. Even worse, as we will see, he is frequently forced to work at a job not of his choice and which he therefore must certainly hate. And he lives in a condition of unbelievable overcrowding, with hardly ever a chance for privacy. To put it mildly, such a man must seethe with resentment and hostility.

Now against whom would it be more logical for the citizens of a socialist state to direct their resentment and hostility than against that very socialist state itself? The same socialist state which has proclaimed its responsibility for their life, has promised them a life of bliss, and which *in fact* is responsible for giving them a life of hell. Indeed, the leaders of a socialist state live in a further dilemma, in that they daily encourage the people to believe that socialism is a perfect system whose bad results can only be the work of evil men. If that were true, who in reason could those evil men be but *the rulers themselves*, who have not only made life a hell, but have perverted an allegedly perfect system to do it?

It follows that the rulers of a socialist state must live in terror of the people. By the logic of their actions and their teachings, the boiling, seething resentment of the people should well up and swallow them in an orgy of bloody vengeance. The rulers sense this, even if they do not admit it openly; and thus their major concern is always to keep the lid on the citizenry.

Consequently, it is true but very inadequate merely to say such things as that socialism lacks freedom of the press and freedom of speech. Of course, it lacks these freedoms. If the government owns all the newspapers and publishing houses, if it decides for what purposes newsprint and paper are to be made available, then obviously nothing can be printed which the government does not want printed. If it owns all the meeting halls, no public speech or lecture can be delivered which the government does not want delivered. But socialism goes far beyond the mere lack of freedom of press and speech. It totally *annihilates* these freedoms. It turns the press and every public forum into a vehicle of hysterical propaganda in its own behalf, and it engages in the relentless persecution of everyone who dares to deviate by so much as an inch from its official party line.

The reason for these facts is the socialist rulers' terror of the people. To protect themselves, they must order the propaganda ministry and the secret police to work 'round the clock. The one, to constantly divert the people's attention from the responsibility of socialism, and of the rulers of socialism, for the people's misery. The other, to spirit away and silence anyone who might even remotely suggest the responsibility of socialism or its rulers—to spirit away anyone who begins to show signs of thinking

for himself. It is because of the rulers' terror, and their desperate need to find scapegoats for the failures of socialism, that the press of a socialist country is always full of stories about foreign plots and sabotage, and about corruption and mismanagement on the part of subordinate officials, and why, periodically, it is necessary to unmask large-scale domestic plots and to sacrifice major officials and entire factions in giant purges.

It is because of their terror, and their desperate need to crush every breath even of potential opposition, that the rulers of socialism do not dare to allow even purely cultural activities that are not under the control of the state. For if people so much as assemble for an art show or poetry reading that is not controlled by the state, the rulers must fear the dissemination of dangerous ideas. Any unauthorized ideas are dangerous ideas, because they can lead people to begin thinking for themselves and thus to begin thinking about the nature of socialism and its rulers. The rulers must fear the spontaneous assembly of a handful of people in a room, and use the secret police and its apparatus of spies, informers, and terror either to stop such meetings or to make sure that their content is entirely innocuous from the point of view of the state.

Socialism cannot be ruled for very long except by terror. As soon as the terror is relaxed, resentment and hostility logically begin to well up against the rulers. The stage is thus set for a revolution or civil war. In fact, in the absence of terror, or, more correctly, a sufficient degree of terror, socialism would be characterized by an endless series of revolutions and civil wars, as each new group of rulers proved as incapable of making socialism function successfully as its predecessors before it.

The inescapable inference to be drawn from this discussion is that the terror actually experienced in the socialist countries has not been simply the work of evil men, such as Stalin, but springs from the nature of the socialist system, and at least in those socialist countries which are not committed to the abandonment of socialism, *is still going on at this very moment*. (As of the fall of 1994, this is certainly the case in China, Cuba, North Korea, Laos, Cambodia, and Vietnam. Despite claims of commitment to the abandonment of socialism, it may very well still be the case both in portions of the former Soviet Union and in some of the former East European satellites.) Stalin could come to the fore because his unusual willingness and cunning in the use of terror were the specific characteristics most required by a ruler of socialism. He rose to the top by a process of socialist natural selection: the selection of the worst.²⁴ His heirs resorted to the same techniques. As well-known examples, consider the invasions of Hungary and Czechoslovakia, the use of drugs to destroy the sanity of dissidents, and, above all, the vast network of forced labor camps in

the Soviet Union. And, of course, even in the last years of socialism, there was no way of knowing what was not reported to the outside world, which almost certainly was a good deal worse than what was reported. Indeed, most of the territory of the Soviet Union was inaccessible to foreigners, and contacts with Soviet citizens were severely limited by the Soviet government.²⁵ The Soviet government pursued this policy of secrecy only because it had a great deal to hide. The policy of secrecy has now apparently been abandoned by the successor regime, and it is to be hoped that the full truth of the atrocities committed in the Soviet Union under socialism will emerge in the years to come.

Under the Soviet regime, the Russian people experienced all the hostility and resentment I have described, but they were so fearful and behaved so contemptibly that they channelled it against each other rather than against socialism and its rulers. Hedrick Smith wrote: “. . . Soviet society in general is peopled by mini-dictators inflicting inconvenience and misery on the rest of their fellow citizens, often, it seems, as a way of getting back at the system for the hardship and frustration they themselves have suffered.”²⁶ He quotes a Russian scientist: “Put a Russian in charge of a little plot of ground or a doorway somewhere, and he will use his meager authority over that spot to make life hard on others.” Smith notes that he has heard Russians describe this phenomenon as “a mass settling of scores on a personal level.”²⁷

This is the psychological and moral climate of a socialist society—a society blinded by terror and reduced virtually to the punishment of all by all. It is terror and universal hatred that socialism and its rulers require lest they be blasted from power.²⁸

If Stalin’s heirs did not find it necessary to be fully as brutal as Stalin himself, it was only because they were able to coast on the environment of fear and the habit of unquestioning obedience that he created. But in the prolonged absence of fresh demonstrations of terror on the scale applied by Stalin, and as the result of the relaxation inspired by Gorbachev, more and more resentments surfaced and came to be focused on the government. Thus, the stage was set for the collapse of socialism.

It was to be expected that to avoid such collapse, the Soviet government would return to its traditional policy of all-out repression. Fortunately, the attempt to do this failed—in the aborted coup of August 1991. However, similar, more successful attempts by the remnants of the Communist apparatus cannot be ruled out and may well take place in the future.

The only alternative both to renewed repression and to an unending series of civil wars and revolutions, as successive socialist governments attempt the impossible and are driven out in a storm of hatred, is to abandon

socialism in favor of capitalism. Whether or not Russia and the other portions of the former Soviet Union will find the will to make such a historic change, or even be allowed to make it by a citizenry that is intellectually still committed to socialism, remains to be seen. Thus far, the economic reforms enacted constitute but the faintest beginning of such a change.

In Eastern Europe, where the end of fear of Soviet invasion led to the quick loss of the satellites, the prospects for establishing capitalism appear to be better. This is especially true in what was formerly East Germany, where the unified German government is in a position to provide genuine guarantees of property rights. Hopefully, at least Hungary, Czechoslovakia, and Poland, and the Baltic states of Lithuania, Latvia, and Estonia, which were so recently part of the Soviet Union, will also be able to succeed in establishing capitalism. The nature of the requirements for establishing capitalism in a formerly socialist country will be explained at the end of this chapter.

4. The Necessity of Forced Labor Under Socialism

Socialism necessitates a system of forced labor—slavery. Forced labor is implied in the very idea of socialist planning. If the state is to plan the production of all commodities, it must also plan the skills that the workers will possess who are to produce those commodities, and where those workers are to live and work. It is incompatible with socialist planning for private individuals to have the freedom to acquire the skills *they* want and to live where *they* want. Such freedom would alone make socialist planning impossible.

Of course, socialism cannot plan in any case. Nevertheless, forced labor remains an essential feature of socialism. As shown in Part A of this chapter, the economic conditions of socialism are the same as those which prevail under universal price controls and universal shortages. Accordingly, socialism is characterized by a labor shortage, in which there is a ready and waiting employment for more labor in the production of virtually every good. The labor shortage under socialism results from the fact that a socialist government wants to expand production, but is unable to trace the connections among the different industries; it is unable to determine the effects of producing more of any one item on the ability to produce other items.

As a result, as we have seen, it establishes a quota system, as in Soviet Russia, in which it tries to encourage the maximum possible production of *each* item. This creates a need for additional labor and all other factors of production in every industry and factory. The labor shortage is compounded by all of the inefficiencies of

socialism, which cause a larger amount of labor to be required to produce each unit of a good. Finally, the shortages of consumers' goods under socialism act to reduce the supply of labor by destroying the incentive to work and earn money, leading people to stop working.²⁹

In the face of such conditions, if the government is unwilling to abandon socialism (or price controls, however the case may be), its only alternative is *to freeze people into their jobs, order them into those jobs and those geographical areas where it considers their work vital, and extract work from them by the threat of physical force*. The government must freeze people into their jobs to stop them from quitting in response to the shortage of consumers' goods. It must order them into specific jobs in specific areas for the same reasons it finds it necessary when a shortage exists to allocate crude oil or any other factor of production to the production of specific products in specific places, namely, to avoid the chaos of products it considers vital not being produced because other products it considers less important are produced instead. It must extract work by the threat of force because, with the money that jobs offer no longer a value to the workers, it lacks adequate positive incentives to offer them.

This, of course, is a system of slavery.

Forced Labor in the Soviet Union

It is necessary to consider the extent to which forced labor existed in the Soviet Union.

First and foremost, over the life of the Communist regime untold millions of people suffered and died in concentration camps—the infamous Gulag system. In the Stalin years, the camps may have held as many as 20 to 30 million slave laborers.³⁰ Even as late as the Gorbachev era, the camps contained hundreds of thousands if not a million or more slave laborers. Second, forced labor existed insofar as all people living on collective farms—as much as 40 percent or more of the Soviet population—were prohibited from moving away from those farms without the permission of the collective farm managements. In addition, at harvest time, all available urban workers could be forced into the countryside to help bring in the harvest. (Observe, incidentally, that the collective farming system was so inefficient that 40 percent of the population was insufficient to bring in the harvest. In the United States, by way of comparison, less than 4 percent of the population is more than sufficient for agriculture.) Third, every graduate of a university or technical school in the Soviet Union was compulsorily assigned to a job for a period of two to three years following graduation. Fourth, every remaining worker in the Soviet Union was compelled to have a labor book that detailed all of his previous employment, including com-

ments by the government officials who were his former employers, reasons for changing jobs, and so on. This book had to be presented to each new government employer. Employment could not be obtained without it. The new government employer then kept the book so long as the worker was employed at that particular job. Theoretically, since Khrushchev, the government employer was supposed to return the labor book at the worker's request. Nevertheless, this system certainly discouraged the worker's leaving any given job against the government employer's wishes, and was, in fact, a forcible deterrent to changing jobs. In addition, it was illegal in the Soviet Union to be unemployed.³¹

If the severity of forced labor in Soviet Russia under Stalin's successors was not as great as it was under Stalin, the explanation was largely a more flourishing black market. In the latter part of the Brezhnev era, for example, the black market was estimated to account for about 20 percent of the Soviet Union's economy.³² In addition, for many years following Stalin it was legal for the members of collective farms to farm small plots of up to an acre on their own account and to sell the produce in the cities for whatever prices it could bring. These small plots accounted for less than 3 percent of the cultivated land in the Soviet Union and produced about 30 percent of its agricultural output.³³ This agricultural output and the black market made it worthwhile for people to work and earn money; within limits they provided people with something to spend the money on.

Notice, however, how the mitigation of forced labor and, indeed, the very survival of the socialist system, depended on the extent to which socialist principles were violated. Strictly, according to socialist principles, there should have been no black market and no quasi-private farming plots. But it was only by permitting them that the system could survive. For the rest, the fact that forced labor was not as severe as it was under Stalin was the result of a willingness on the part of Stalin's successors to tolerate enormous rates of labor absenteeism and a general breakdown of what the regime called "labor discipline."³⁴ (To illustrate how pervasive these problems were, Hedrick Smith described a popular comedy routine in Russia, in which three workers sneaked away from their jobs to get haircuts. They received miserable service because their barbers had sneaked off too. The barbers, in turn, could not obtain the things they wanted, because the dentist, repairman, and grocer they were seeking were the very customers left sitting in their chairs.³⁵)

The Imposition of Forced Labor in the United States

It must be stressed that a system of forced labor could be imposed even in the United States. This could happen

either as a result of the open socialization of the economic system, or, as is much more likely, as part of a program of *de facto* socialization carried out in response to the chaos created by price controls. None of our traditions, none of our past record of freedom, would be enough to stop it.

It should be realized that such slavery was actually instituted during World War II in countries with very similar traditions as the United States. It was imposed in Great Britain, Australia, and even Canada. During World War II, workers in those countries could not quit or change their jobs without government permission, and they could be ordered to work wherever the government required them. Similar legislation was proposed to the Congress of the United States by President Roosevelt in his State of the Union Message of January 1944.³⁶ Fortunately, the legislation did not pass. But had the United States been at war longer and the effects of the labor shortage become more severe, as a result of the continued operation of inflation and price controls, it is very likely that such legislation would have been enacted even here. For the only alternative, given the continuation of price controls, would have been chaos in the allocation of labor and the massive stoppage of work.

Thus, if we someday adopt socialism in this country, no matter what its form, we must expect the same consequences as existed in the Soviet Union.

5. Socialism as a System of Aristocratic Privilege and a Court Society

Once the government assumes the power to determine the individual's job, it obtains the power to decide whether he must spend his life working in a coal mine in a remote village somewhere, or in the comparative comfort of one of its offices in the capital. It obtains the power to decide whether he will pass his life as an obscure nobody living in poverty, or enjoy a flourishing career, celebrated in his field, and living in comparative opulence.³⁷ This, of course, goes along with the government's power over the distribution of consumers' goods—a power which every socialist government naturally possesses. In accordance with its powers of distribution, a socialist government decides what kind of house or apartment the individual is to occupy, what kind of clothing he is to wear, what kind of food he is to eat, whether or not he is to own an automobile, and so on.

In Soviet Russia, for example, the government assigned different grades of housing based on rank in the government or Communist Party. On the same basis, it decided who could and who could not buy an automobile. It even maintained special stores that were closed to the general public and which exclusively served high

government and party officials and their favorites in the arts and sciences. These stores carried many kinds of Western imports, from clothing to tape recorders, and the limited supplies of whatever worthwhile goods as were produced in the Soviet Union itself. While such things as meat were unavailable throughout most of the Soviet Union for months on end, the privileged customers of these stores were supplied with caviar.³⁸

The existence of a system of naked aristocratic privilege is not a contradiction of the principles of socialism, but their natural outgrowth. It follows directly from socialism's fundamental moral and political premise, which is that the individual does not exist as an end in himself, but as a means to the ends of "Society." Since Society is not an independent entity with a will and voice of its own, the alleged ends of Society are necessarily ends determined by the rulers of the socialist state. This means that under socialism the individual is actually nothing more than a means to the ends of the *rulers*. It is difficult to imagine a system that could be more aristocratic and servile in nature.

The existence of a system of aristocratic privilege does not contradict the slogan "from each according to his ability, to each according to his need."³⁹ The rulers of socialism can and do assert that they and their favorites have "special needs." Moreover, that slogan was intended by Marx to be achieved only under "socialism in its higher phase"—that is, after generations of socialism had changed human nature. If one thinks seriously about the meaning of the phrase "a change in human nature," one must realize that it is a contradiction and therefore impossible. A change in human *nature* is as absurd an idea as a change in the nature of water or lead. Men will be able to practice the principle "from each according to his ability, to each according to his need," when water is able to flow uphill and lead to float. Meanwhile, while it is waiting for human nature to "change," a socialist state is free to adopt any system of distribution it pleases. Moreover, it cannot, as a matter of practice, adopt a system of economic equality, because, as previously explained, such a system is tantamount to the destruction of causality in production—it renders the individual incapable of accomplishing results perceptibly affecting his or his loved ones' well-being and thus would have the consequence of immediately bringing production to an end.⁴⁰

What positively generates the system of aristocratic privilege under socialism is the fact that the only values that actually count in a socialist society are the values of its rulers. It should be recalled from Part A of this chapter that the absence of competition and profit-and-loss incentives in supplying the consumers makes the plain citizens economically impotent under socialism. Produc-

tion thus takes place exclusively in accordance with the values of the rulers. What the rulers value is what contributes to their military strength, their prestige, and their amusement. The goods required by the masses for survival enter into the rulers' valuations only to the extent that the rulers need subjects and do not wish to lose too many of them.

The nature of the rulers' values determines the nature of the incentives and inequalities of a socialist society. It is not true that a socialist society exists entirely without incentives. That would be true only if it tried to practice consistently the absurd ideal "from each according to his ability, to each according to his need." In actual fact, a socialist society does have some incentives. But the incentives are geared entirely to the achievement of the values of the rulers. There are no incentives to the achievement of the values of the plain citizens.

The kind of incentives and inequalities that prevail under socialism are similar to those which prevail in an army. In an army there are incentives for privates to make corporal and for everyone to advance to a higher grade. But all the incentives in an army are geared to achieving the objectives of the supreme commander. The objectives of the supreme commander are the ultimate ends, definitely not the improvement of the life of the privates. Indeed, neither in an army nor under socialism is the improvement of *anyone's* actual life the goal. The goal is always some impersonal achievement, whether victory in the battle with the neighboring country or victory in the battle of the new dam or truck factory, which is just how the socialists in Soviet Russia described their construction projects.⁴¹ The closest socialism ever comes to making the improvement of life its goal is its alleged concern with the improvement of the life of unborn future generations. But no sooner does the generation of the grandchildren arrive, than socialism's concern switches to the grandchildren of the grandchildren.⁴²

Socialism is essentially a militaristic-aristocratic type society. It rests on a base of starving serfs, comprising the great majority of the population, who live at or below the level of minimum physical subsistence and whose only function in life is to toil for the values of the rulers. Workers with special skills of value to the rulers may be somewhat better off, if that is what is necessary to make them deliver their skills and if it is practicable to offer them such incentives. But they too are essentially just serfs—they too work under force, and what they receive is subsistence or sub-subsistence, plus a small bonus for their skill. Above the serfs come various grades of officials and favorites, who help the rulers to exploit the serfs or who provide the rulers with weapons of war, the means of gaining greater prestige, or simply amusement. In this category are all the production managers, all the lower

and middle party and police officials, the propagandists, the intellectuals, the scientists, the artists, the athletes. These are the tools, the henchmen, the flunkies, and the simple court favorites of the socialist society. Finally, at the very top, come the supreme rulers themselves—the men who have outmaneuvered and outgunned all of their rivals. These are the Neanderthals whose powerlust and gluttony socialism elevates to the ultimate end of human existence.

A few further words need to be said in reference to the middle strata of a socialist society, especially its intellectuals. As a result of a socialist state's twin powers over the individual's work and consumption, everyone's life comes to depend unconditionally on the good graces of every government official with power or influence. In such circumstances, not only are people stopped by terror from criticizing anything the government or any government official does, but a competition breaks out in the positive *praise and adulation* of the government and its officials. As illustration of the lengths to which such self-abasing flattery can be carried, it should be remembered that educated Germans proclaimed that Hitler spoke with God, the "Führer of the Universe"; and that educated Russians praised Stalin as "the leader genius," the sight of whom made them want "to howl from happiness and exaltation."⁴³

The same sort of thing continued to go on in Soviet Russia almost to the very end, though, since the time of Khrushchev it was more subdued. In Soviet Russia, no one was able to rise in his field without the backing of influential friends in the Party. Major advancement, including the highly coveted privilege of travelling abroad and thus being able to buy foreign goods simply unavailable in Soviet Russia, required serving as an informer for the KGB—the secret police. In the Soviet Union, men betrayed friends and relatives for the meanest material gains: to be able to buy such things as a Western refrigerator, Western furniture, even a Western toilet.⁴⁴

Ironically, the American sympathizers of the Soviet Union, who continue to work for the establishment of a similar regime here, frequently write books and plays denouncing corporate executives under capitalism for allegedly selling their souls for material advantage. The socialist society that these authors and playwrights yearn for is a society in which the only way that intellectuals can advance is by means of displaying the most abject servility to Neanderthals, who, in the absence of a capitalist world outside, could offer them no more than a few extra scraps of food wrung from some poor serf. It is pitiable, but that is evidently the path that many of today's intellectuals find most secure and the reward they find commensurate with their abilities, since a socialist

society is what they are striving to bring about.

Such intellectuals should not be thought of, however, as motivated by a desire to sell their souls merely for a crust of bread or a toilet. They describe themselves as nonmaterialists, and what they seek is primarily a non-material reward. The nature of that nonmaterial reward makes a crust of bread or a toilet appear far too generous as a measure of their worth. For, as we have seen in the discussion of environmentalism, what they are motivated by is simply the nihilistic desire to destroy human achievement. Their nonmaterial reward is to be the impoverishment and suffering of all.⁴⁵

6. From Forced Labor to Mass Murder Under Socialism

There is a further consequence of forced labor under socialism that must be considered, namely, its potential for developing into mass murder. To understand how this can happen, we must contrast forced labor under socialism with forced labor under different conditions.

Slavery existed in ancient Greece and Rome and in the Southern United States before the Civil War, and was, of course, a moral abomination. Nevertheless, abominable as slavery was, there was an important factor in these cases which restrained the slave owners and the overseers in their treatment of the slaves. That was the fact that *the slaves were private property*. A private slave owner was restrained in his treatment of his slaves by his own material self-interest. If he injured or killed his slave, he destroyed his own property. Of course, out of ignorance or irrationality, this sometimes happened; but it was the exception rather than the rule. Private slave owners were motivated to treat their slaves with at least the same consideration they gave to their livestock, and to see to it that their overseers acted with the same consideration.

But under socialism, the slaves are “public property”—the property of the state. Those who have charge of the slaves, therefore, have no personal economic interest in their lives or well-being. Since they are not owners of the slaves, they will not derive any personal material benefit if the slaves are alive to work in the future, nor suffer any personal material loss if the slaves are not alive to work in the future. In such conditions, slave labor results in mass murder. The officials in charge of the slaves are given orders to complete certain projects as of a certain time. Quite possibly, they are threatened with being reduced to the status of slaves themselves, if they fail. In these circumstances, the slaves are treated as valueless natural resources. Brutal punishments are inflicted on them for trifling reasons, and they are worked to the point of exhaustion and death. The slaves of

socialism are slaves, but they are no one’s property and therefore no one’s loss.

In this way, slave labor under socialism results in mass murder. In just this way, tens of millions of people have been murdered.

Of course, the economics of slavery under socialism is not a sufficient explanation of mass murder. Those who participate in the system must be utterly depraved. But observe how socialism creates the conditions in which depravity flourishes—the conditions in which depravity can express itself, is freed of the restraints of better motives, and is positively nurtured and encouraged. For it is socialism that delivers men into slavery. It is socialism that removes the restraint of self-interest from those in charge of the use of any form of property. And it is socialism that creates an environment of hatred and sadism. In such conditions, the most depraved and vicious element of the population finds a place for its depravity and viciousness and steps forward to run the labor camps and the whole socialist society.

7. From Socialism to Capitalism: How to Privatize Communist Countries

The worldwide discrediting of socialism and the desire to replace it with capitalism raises the vital question of precisely how to establish private ownership of the means of production in the socialist countries. The purpose of this section is to explain not only how state property can initially be placed in private hands, but, even more importantly, what is required for private ownership of the means of production to be made genuine and effective.

The advantages of private ownership of the means of production are so overwhelming that it is actually of secondary importance precisely who the initial private owners are and how their ownership is established. Whatever the specific method or methods of establishing private ownership of the means of production, the institution will function to the benefit of everyone—owners of the means of production and *nonowners* of the means of production alike.⁴⁶ It will do so, however, only to the degree that the individual private owners possess *full and secure rights of ownership*.

The security of property rights means that the owners must be secure both against the possibility of any form of new confiscation by the state and against successful challenge to their ownership by other private individuals claiming to be the rightful owners. To understand the necessity of the security of property rights, the reader should imagine how his behavior would be affected if he were contemplating buying a home that he could not be certain would be his for very long. He would not be

prepared to pay very much for it, and, after he bought it, he would not be prepared to put very much into it. Indeed, his incentive would probably be to let the house run down and even to sell off such things as the appliances for the sake of obtaining cash or other assets that would be more securely his. Without the security of property rights, the situation of all would-be owners of factories, farms, mines, and stores in the present-day socialist countries must be exactly the same. Such owners would be in essentially the same position as the state employees described earlier who were supposed to act as capitalists under “market socialism.”⁴⁷ The absolute security of the owners’ property rights is essential if people are to be willing to pay proper prices for the various properties and then to stay on and improve them rather than milk them for whatever they can.

An essential aspect of the rights of ownership is the right freely to buy and sell property. This aspect of property rights is especially important in the transition from socialism to capitalism. The combinations of assets of the various enterprises of socialism and thus the combinations of assets of the enterprises that will initially exist under capitalism will almost certainly need radical change. It will be essential for the market to have the freedom literally to redefine all enterprises by changing the combinations of their assets. This means, there must be the freedom both to break up existing enterprises by selling off their assets in the manner of “corporate raiders” and to combine their assets through such devices as mergers and acquisitions.

As I say, these freedoms are essential. For a major foundation of the efficiency of capitalism—ironically, increasingly overlooked in the supposedly capitalist United States—is the ability to create business firms that possess *the right combinations of assets*. This ability is essential if firms are to be able to produce the right products by the most efficient methods. It must be present at all times, if the economic system is to be able to adjust to changing conditions. It is acutely necessary in the context of putting right the combinations of assets that a socialist government is likely to have thought appropriate for the various enterprises. It would be essential not only for such things as combining manufacturers with the right parts makers, and retail outlets with the appropriate warehouse facilities, but also for changing the uses made of all kinds of existing factories and land sites.

Nothing less than a radical overhaul of the entire apparatus of production inherited from socialism will be necessary if the economic system is to become efficient. Many factories will have to be closed and such of their assets as are still useable, devoted to production in different locations. Most other factories will have to undergo major changes in what they produce and the methods

by which they produce. The output of innumerable factories will have to go to different users. The use that is made of innumerable land sites will have to change. All of this requires the freedom to buy and sell and to breakup and combine the assets of firms.

Along the same lines, the market would need the absolute freedom to hire and fire the managers of enterprises. This freedom too is necessary at all times and acutely necessary in the conditions of a transition from socialism to capitalism. Any managers inherited from socialism are likely to need replacement. Many of the initial managers under capitalism will also need replacement. To be effective, the transition from socialism to capitalism will need to be followed by a fall into obscurity of numerous former top managers and rise from obscurity of numerous new managers. Nothing must be allowed to impede the business takeovers and buyouts that are an essential part of this process.

In addition, of course, there must be the absolute freedom to hire and fire ordinary workers. Socialism is characterized by a massive misallocation of labor, just as it is characterized by massive misallocation of capital. This too must be put right if production is to become efficient.

A vital aspect of the transition from socialism to capitalism, that is implicit in all that has just been said and is clearly called for by the nature of capitalism, is the freedom of every enterprise to enter into the industry of every other enterprise, and, of course, the freedom of everybody to form new enterprises. In other words, the full freedom of competition must exist.

In the light of these requirements, the specific methods of establishing private ownership of the means of production can now be considered.

The simplest and most obvious method is that wherever former owners of property or their descendants are still alive, the properties should be returned to those from whom they were stolen, or to their descendants.

In Eastern Europe, this method is somewhat complicated by the fact that many of the private property owners who were dispossessed by the Communists were themselves beneficiaries of expropriations carried out not long before by the Nazis. Here the solution clearly is to return the properties to the earlier owners dispossessed by the Nazis, or to the descendants of those owners.

To the difficulty of settling claims as between two or more private claimants is added the fact that the method of returning property to former owners becomes less and less adequate, the longer is the period of time during which socialism has existed and the more ruthless were the means employed to establish socialism in the first place. This is because it becomes correspondingly more difficult to locate specific individuals with valid claims

to ownership. (In many cases, everyone with a valid claim may simply have been murdered.) The major part of the problem, however, is the fact that as time has passed, numerous new plants and machines have been constructed, which no one can now claim on the basis of property rights existing before the establishment of socialism. These observations are particularly applicable to the former Soviet Union, where socialism existed for over seventy years and where over twenty million people were murdered by the Communist regime. The mass murders committed by the Nazis may pose a similar problem to the location of heirs.

In view of these facts, I propose three methods of privatization. First, as far as possible, property should be returned to those from whom it was stolen, or to their descendants. Second, in the case of agricultural land where it is not possible to locate former owners or their descendants, the land should be made the individual private property of those who now work it. That is, all the collective farms and state farms should be broken up into separate, individual private farms. Formulas could be devised allowing for differences in the amount of land individuals received based on differences in the time they had been compelled to work the land. Those who had suffered such forced labor for a longer period, would receive more of the land than those who had suffered it for a shorter period. Individuals who would otherwise receive parcels of land too small to farm might simply receive cash.

Third, in the case of all other property—factories, mines, shops, and so forth—the appropriate principle would be to place the assets on the open market for competitive bidding. Foreigners should be actively encouraged to participate in this bidding and, indeed, the bidding should be carried on in Western currencies and in gold. Foreigners should have the same full rights of ownership as citizens: they should be allowed to buy and sell property of all kinds, to form companies, and to remit dividend and interest payments to their own countries to whatever extent they wish.

Active foreign participation in the bidding creates the possibility of the average citizen of the socialist countries deriving an important immediate benefit from privatization. Namely, as the proceeds from the sale of assets came in, each individual citizen could receive his individual share of the proceeds—that is, the proceeds of the government's sales could be divided up among the citizens. Thus, during the period of liquidation of state assets, the average citizen could receive one or more checks payable in Western currencies. He could use the proceeds to buy essential consumers' goods that could be imported from the outside world because the means would be present to pay for those imports. This would help to tide

him over during the difficult period of transition during which his country's economic system was being reorganized and he was unemployed or not in a position to earn a significant amount by working. In this way, for the first and only time—in the process of its liquidation—collective ownership of the means of production would turn out to provide some actual benefit to the citizens: in the moment of its being liquidated for Western cash, it would enable them to obtain something of value to their lives.

It should be observed, incidentally, that the benefit to the average citizen would be the greater, the greater was the prospective security of property. Because to the extent that newly acquired property rights were expected to be upheld, the higher would be the prices that foreigners would be prepared to pay for the assets being offered for sale, and thus the greater would be the proceeds accruing to the average citizen of the formerly socialist country. Economic morality would be rewarded. (The ability of foreigners freely to remit dividends and interest payments is an important aspect of this morality and also an important foundation of the foreigners' willingness to bid up the prices of the assets offered for sale, and thus of the ability of the average citizen of the formerly socialist country immediately to benefit from privatization.)

The next chapter will show why it is of absolutely no consequence that much of the property of the formerly socialist country would be owned by foreigners—why there are no negatives to offset the positives I have just described, but only the further positives resulting from the operation of private ownership of the means of production once it is in place. Furthermore, once the transition to capitalism was accomplished and the average citizen of the formerly socialist country was in a position to begin saving and investing on a significant scale, not only would he begin to accumulate capital within his own country, but the capital market of the entire world would be open to him, and he could invest abroad just as others had invested in his country. This is an aspect of what can be called capitalist internationalism.

In order to secure the best prices for assets being sold off, a corps of professional auctioneers and brokers should be employed, who would receive a commission based on a percentage of the sales proceeds.

The principle of distributing the proceeds from the sale of assets equally among the citizens could be modified to give greater compensation to victims of labor camps and survivors of those who have been murdered by the Communist regime. However, the primary compensation for such crimes should probably be left until after the transition to capitalism has been completed and it is thus possible to provide more substantial compensation.

There are, of course, other possible methods of establishing private property. One would be simply to make

the various existing enterprises the private property of their present managements. Another would be to turn the various enterprises over to their present employees. Obviously, the two methods could be combined, with the present managers receiving a certain percentage of the ownership and the present employees a further percentage. To some extent, these methods are actually in use.

If, following the establishment of private property in these ways, there really was security of property and full rights to buy and sell assets and shares, to hire and fire managers and workers, and to compete in all branches of industry, these methods would ultimately be effective in establishing private ownership of the means of production. As time went on, all the necessary changes could take place, including changes in ownership, which would be effected by the market, and an efficient economic system would emerge. However, the appropriation of enterprises by their Communist-appointed managers will necessarily carry with it the taint of the old regime and all of its injustices, and is likely also to be accompanied by a continued large-scale ability to use political pull, based on previously established relationships with government officials. Thus, private ownership of the means of production begun in this way will be tainted by injustice, past and present, and by corresponding inefficiency. This would be a legitimate source of resentment and would constitute a potential threat to the continuation of such ownership.

Turning the ownership of each establishment over to the workers of that establishment would at best arbitrarily favor some workers over others. Those workers who happened to work in highly capital-intensive industries, such as electric-power production or steel making, would obtain ownership of far more capital than workers who happened to work in less capital-intensive industries, such as clothing factories and restaurants. The same point would apply within each industry, insofar as some plants were more modern and efficient than others. It is very pertinent, of course, that as the result of socialism's protracted gross inefficiencies, the value of many factories and other productive establishments would turn out to be altogether nonexistent.

The problem of workers benefitting or failing to benefit by virtue of the accidental circumstances of where they worked would also exist in agriculture. The workers of collective farms with abundant, rich soil would receive more than the workers of collective farms with relatively meager, poor soil. In agriculture, however, apart from the return of former owners or their descendants, there does not appear to be an alternative to the workers' coming to own the land. Of course, the workers on the relatively poorer lands could be given the option of sharing in the proceeds of the sale of other assets rather

than accept land they had been forced to work.

To the extent that workplaces do become the property of the workers employed in them, it must be stressed that it is vital that the workers of each plant be free both to sell their ownership shares while keeping their jobs and to leave their jobs while keeping their shares. In this case, ownership and employment would eventually become almost entirely separate, as under capitalism. The ability to hold ownership and employment separately is essential for the free movement of capital and labor between industries. In its absence, workers would be reluctant to leave their employment, because they would then lose their capital, and they would be afraid to admit new workers into their firm or industry, because they would then have to correspondingly dilute their ownership. There would be no possibility of transferring capital from one industry to another, since the workers of the industry from which the capital came would simply lose it. Furthermore, the rapid separation of ownership and employment is necessary to overcome a bias that might otherwise exist against improvements in efficiency if workers as owners were in a position to reject improvements that might cost them their jobs.⁴⁸

Thus, at its worst, turning ownership over to the workers could mean a state of affairs in which the movement of labor and capital between the various branches of industry was made impossible. In addition, it could mean a situation in which the workers of each industry, by virtue of their possession of a monopoly on employment in their industry, were in a position to practice extortion on the rest of the economic system as the price of providing their services. Obviously, these are conditions which should be avoided at all costs.⁴⁹

Provided that the essential requirements of security of property, the separation of employment and ownership, and the unrestricted freedoms to buy and sell, hire and fire, and compete, are observed, what remains is to accomplish the transition to private ownership as quickly as possible. Reasonable but strict time limits must be set for the location of former owners or their heirs, and it must be firmly established that thereafter no new claims will be heard on their account. This is an essential part of establishing the security of property. All of the assets in the hands of the state must likewise be disposed of within a strict time limit, so that no one in the market need labor under any uncertainty about what properties will be available and when and thus what plans he can and cannot make. This is essential to making the economic system as efficient as possible as soon as possible.

In the absence of the establishment of private ownership of the means of production, all other reform is meaningless. For example, decontrolling prices without first establishing private ownership of the means of pro-

duction and its corollary the freedom of competition, simply means giving arbitrary, monopolistic power to lesser government officials in charge of individual industries and enterprises. It is comparable to giving the postmaster general or the local postmaster the right to set postal rates. Without private ownership of the means of production, there can be no market economy or free market. Divorced from private ownership of the means of production, such notions are a contradiction in terms. Nor, of course, can there be lasting or meaningful reform in the political realm. As shown earlier in this chapter, political freedom cannot exist without private ownership of the means of production both in such specific forms as printing presses and lecture halls and in general, throughout the economic system, in order to secure the

individual's livelihood from the power of the state. If the present, avowedly anticommunist regime in Russia does not soon succeed in establishing large-scale private ownership of the means of production, it will be certain to begin taking on all of the odious features of the Communist regime it has replaced. Indeed, one authority claims that 150,000 people are in jail even now in Russia for having engaged in black market activity.⁵⁰

For the rest, it is essential that public opinion come to be based on an understanding of the importance of private ownership of the means of production and why its existence is in the material self-interest of everyone. Such understanding is essential to the long-run security of property. To further promote such understanding is a leading purpose of the next chapter.

Notes

1. On these points, see above, pp. 249–250, 257, and 260–262 passim.
2. See above, pp. 263–264.
3. See Ludwig von Mises, *Socialism* (New Haven: Yale University Press, 1951), pp. 111–142, 211–220, 516–521; reprint ed. (Indianapolis: Liberty Classics, 1981); idem, *Human Action*, 3d ed. rev. (Chicago: Henry Regnery, 1966) pp. 689–715. Von Mises's leading supporter on this issue is F. A. Hayek, to whom I am also greatly indebted in the following discussion. See his *The Road to Serfdom* (Chicago: University of Chicago Press, 1944), pp. 48–50; and *Individualism and Economic Order* (Chicago: University of Chicago Press, 1948), pp. 33–56, 77–91, 119–208.
4. See above, p. 137.
5. See above, *ibid.*

7. See above, pp. 239–240.
8. Cf. Robert Kaiser, *Russia* (New York: Atheneum, 1976), p. 338.
9. See above, pp. 136–137.
10. This point, of course, was made repeatedly by von Mises. See the references to him above, in n. 3 of this chapter.
11. See Kaiser, *Russia*, p. 324.
12. See above, pp. 176–178.
13. *Ibid.*
14. See Kaiser, *Russia*, pp. 330–335.
15. See Hedrick Smith, *The Russians* (New York: Quadrangle/New York Times Book Company, 1976), p. 59.
16. By the same token, the ability of the civilian economy to benefit from government-sponsored weapons research, such as that of the U.S. government in World War II or the U.S. space program in the 1960s, presupposes the existence of a capitalist economic system. It is only the existence of capitalism's profit motive and freedoms of individual initiative and competition that makes it possible to put such research to civilian use. This explains why there were significant civilian benefits in the United States from such research, but not in the Soviet Union, despite the Soviets' early and substantial lead in space research. Needless to say, moreover, in the absence of the need for

- weapons research in a capitalist economy, all of the major scientific and engineering talent that is employed in it, would be employed in other lines of research, and with far greater efficiency, because that research would be privately supported. Thus, for example, in the absence of the development of the atomic bomb, while atomic power would probably not have come as soon, other fundamental advances with other major derivatives would probably have come sooner—it is a case of what Bastiat and Hazlitt refer to as the seen versus the unseen. (See Henry Hazlitt, *Economics in One Lesson*, new ed. [New Rochelle, N. Y.: Arlington House, 1979].) Indeed, with growing government control over research—its seizure of so much of the funds that would otherwise support private research and its politicizing of so much of research—the alternative private research that might have been may simply never be.
17. On this point, see above, pp. 136–137.
18. See above, pp. 258–262. For a detailed explanation of the dependence of capital accumulation on economic efficiency and, more fundamentally, on economic freedom, see below, pp. 634–636.

CHAPTER 9

THE INFLUENCE OF THE DIVISION OF LABOR ON THE INSTITUTIONS OF CAPITALISM

PART A

PRIVATE OWNERSHIP OF THE MEANS OF PRODUCTION

1. The General Benefit from Private Ownership of the Means of Production

The influence of the division of labor on the institution of private ownership of the means of production is almost universally ignored. Typically, people think of privately owned means of production in terms that would be appropriate only in a non-division-of-labor society. That is, they think of them in the same way that they think of privately owned consumers' goods—namely, as being of benefit only to their owners. They believe that before the nonowners can benefit from the means of production, they must first become owners.¹

This belief underlies the popularity of all forms of “redistributionism” and socialism.² People believe that so long as wealth remains concentrated in the hands of a relatively small number of capitalists, the capitalists alone benefit from it. For the great mass of noncapitalists to benefit, it is believed, the wealth of the capitalists must first be taken away and given to the noncapitalists, or be held by the government and used for the collective good of all.

Closely related to these ideas, of course, is the be-

lief—held virtually as a self-evident axiom—that capitalism is a system which operates only in the interests of the capitalists, and that the defenders of capitalism must therefore either be capitalists themselves or be in the pay of the capitalists, or else simply be perverse enemies of the great majority of mankind. So deeply rooted are such convictions that it is often thought to be a sufficient refutation of the arguments of an advocate of capitalism to intimate the size of his bank balance or stockholdings.³

Similarly, in reporting election results, the news media routinely explain voting patterns on the basis of the voters' wealth and income status. They take it for granted that only wealthy, upper-income voters will favor “conservative,” i.e., procapitalist policies, and that poorer, lower-income voters will automatically favor “liberal,” i.e., anticapitalist policies.

Even the alleged friends of capitalism often share the conviction that private ownership of the means of production and capitalism serve only the capitalists: very often their notion of how to fight the spread of communism is first to create more capitalists. Only then, they believe, will there be a sufficient number of people with an interest in opposing communism.

The Benefit of Capital to the Buyers of Products

The first thing that must be realized is that in a division-of-labor society, all private property that is in the form of means of production—i.e., of capital—serves everyone, *nonowners* as well as owners. In a division-of-labor society, the means of production are not used in produc-

ing for their owners' personal consumption, but *for the market*. They are used in producing goods that are *sold*. The physical beneficiaries of this private property—and it is the far greater part of the capitalists' wealth—are all those who buy the products it helps to produce. In other words, it is the general buying public who are the physical beneficiaries of the capitalists' capital.

Consider, for example, the question of who are the physical beneficiaries of the auto plants of General Motors. That is, who physically receives the products of these plants? Is it the stockholders and bondholders of General Motors? Of course not. The number of GM's cars that is produced for the capitalists who own GM is relatively insignificant. Almost 100 percent of General Motors' auto output goes to people who do not own a single share of its stock or a single one of its bonds. The same is true of every other business enterprise.

Indeed, the proportion of General Motors' auto output that is purchased by stockholders or bondholders of any enterprise—by capitalists of any description—out of the proceeds of profit or interest income, is relatively small when compared with the proportion that is purchased by wage and salary earners. The far greater part of the automobiles purchased from GM and almost all other auto manufacturers is purchased by wage and salary earners. Wages and salaries, not profits and interest, are the source of the overwhelming bulk of consumption expenditure throughout a capitalist economy. It is wage and salary earners who consume the overwhelming majority of the automobiles, television sets, housing, furniture, food, and clothing, and almost every other consumers' good that is produced.

Thus, the overwhelmingly greater part of the physical benefit derived from the privately owned means of production in a capitalist economic system goes to nonowners of the means of production—to wage and salary earners.

It cannot be stressed too strongly: the simple fact is that in a division-of-labor society, one does not have to own the means of production in order to get their benefit. One has only to be able to buy the products. In a division-of-labor society, one gets the benefit of means of production *owned by others*—every time one appears in the market as a customer. Indeed, it is of the very essence of a division-of-labor society that one obtains the benefit of others' means of production, just as one obtains the benefit of others' labor and knowledge, and that this occurs by means of the purchase of products in the market. It is only in a non-division-of-labor society, in which there is little or no production for the market, in which the producer and the consumer are almost always one and the same person, that privately owned means of production benefit only their owners, or virtually only their owners.

Implicitly, it is such a society that the enemies of capitalism have in mind. They have not yet woken up to the fact that capitalism is a division-of-labor society. They are unaware that in a division-of-labor society, the means of production serve everyone who buys products, and that thus, under capitalism, *there is a general benefit from the capital owned by the capitalists*—a benefit which everyone shares in his capacity as a buyer of products, even if he himself does not own any means of production or capital.

This general benefit, it should be realized, applies to all of the means of production, not merely to those which are employed in the direct production of consumers' goods. The benefit of the steel mills that produce the steel that enters into GM's cars goes to the buyers of the cars, along with the benefit of the auto plants, as does the benefit of the iron mines that contribute to the production of that steel, and the benefit of the factories that produce iron-mining equipment. The benefit of the land that grows wheat goes to the buyers of bread, as does the benefit of the tractors used in the growing of wheat, and the benefit of the factories which produce those tractors, along with the benefit of the flour mills that make the wheat into flour, and of the bakeries that finally turn out the bread.

Furthermore, if we are to acknowledge the truth, we must recognize that the general buying public, composed overwhelmingly of wage and salary earners, not only obtains the benefit of all of the means of production owned by the capitalists, but exercises real and decisive power over the ways in which those means of production are employed. As was shown in Chapter 6 of this book, it is the general buying public which determines, by its pattern of buying and abstention from buying, which products it is profitable to produce and which it is unprofitable to produce. The buying public thus places the capitalists in a position in which, to make profits and avoid losses, they must produce what it wants to buy, and abstain from producing what it does not want to buy.⁴ In a division-of-labor, capitalist society, it is ultimately the consumers—composed, it cannot be stated too often, overwhelmingly of wage and salary earners—who determine not only the pattern of production, including the relative size of the various industries, but even the specific methods of production used in every industry. For the demand of the consumers determines the relative prices of the factors of production, such as the wages of skilled versus unskilled labor, or the price of copper versus the price of aluminum, and thus which methods of production are more economical in any given case.⁵

The power of the consumers under capitalism is such that businessmen and capitalists are constantly on the

lookout for ways in which they might supply the consumers better. For example, a businessman or capitalist who has invested in a clothing store or clothing factory, in a restaurant, or in the manufacture of breakfast foods, or who is contemplating such an investment, is vitally interested in improving the clothing or the food he sells. He is interested not because he values the satisfaction of others' needs for its own sake, but because he values his own wealth. The only way to increase his wealth, or prevent the competitive improvements introduced by others from decreasing it, is for him to serve his customers better and more efficiently. This, of course, applies to all branches of production that are privately owned and subject to the freedom of competition. It dictates the behavior not only of producers of consumers' goods, but also of suppliers at all stages of production, such as those who sell cloth to the clothing factories, and raw material to the factories which make cloth. For the businessmen who sell to consumers seek to buy means of production that will enable them to produce products of the kind the consumers most want, and to do so at the lowest possible costs of production. The suppliers of these businessmen in turn are obliged to purchase means of production that produce products that best satisfy these criteria. The same principle guides the suppliers of these suppliers, and so on through all stages of production. In other words, the whole system operates so as to produce the best possible products for the final buyers, the consumers, and to do so at the lowest possible costs.

Indeed, as we have seen, even without being bidden, businessmen and capitalists are constantly on the lookout to anticipate any unmet needs of the consumers and to supply those needs. For example, let there be a new residential real-estate development somewhere, and profit-seeking businessmen race to provide the new inhabitants with all the stores they may require, from appliance stores to xerography centers. Let there be any need or desire whatever for whose satisfaction a sufficient number of consumers are willing to pay profitable prices, and, as soon as they become aware of it, as soon as they have discovered it by a process of actively searching out its existence, businessmen and capitalists race to meet that need or desire. This, of course, is in sharpest contrast to conditions under socialism, where, in the nature of the case, no incentives exist for the rulers to serve the general public.⁶

Thus, under capitalism, privately owned means of production are employed for the benefit of all, nonowners as well as owners. They are employed for the benefit of all who buy the ultimate products of the means of production—the consumers' goods—which to the far greater extent represents wage and salary earners. And thus it should be clear that capitalism, the system of

self-interest, works to the interest of all. It is a system of the harmony of self-interests. It is a system in which each, together with any means of production he may own, serves the self-interest of others who in the meanwhile, together with any means of production they may own, serve his self-interest. It is a system in which the individual, and his means of production, serve the self-interests of all those others who *pay* for his products or services, whether those others own means of production or not, which preponderantly they do not to any great extent.

The Benefit of Capital to the Sellers of Labor

It is implicit in much of what I have just said, that there are, in fact, two aspects to the general benefit from the existence of the capitalists' capital. The first of these is the one I have already explained: that of the buyers of products, ultimately consumers' goods, benefitting from the capital directly or indirectly used in the production of those products. The second is in connection with the fact that capital constantly appears in the market as a demand—expenditure—by the capitalists for means of production, including labor. The capitalists begin their productive activities with outlays of money for labor, materials, and equipment. The revenues they subsequently take in from the sale of the products they produce are then almost entirely reexpended in the form of fresh outlays for labor, materials, and equipment. These outlays of the capitalists for labor are what make possible the purchase of products by noncapitalists. They are the incomes of the wage and salary earners.

Thus, there is a twofold benefit to the nonowners from other people's private property in the form of means of production—of capital: Namely, *it is the source of the supply of what the nonowners buy and of the demand for what the nonowners sell.*

It should be obvious that the more economically capitalistic the economic system is, in the sense of the capitalists expending a larger proportion of their sales revenues for means of production and a smaller proportion on their own consumption, the higher will be the income and consumption of wage and salary earners in comparison with the consumption of the capitalists. In other words, the more the capitalists abstain from consumption, in order to accumulate or maintain their capitals, the larger the share of the economic system's output of consumers' goods that goes to wage and salary earners, and the smaller the share that goes to capitalists.⁷

The Direct Relationship Between the General Benefit from Capital and Respect for the Property Rights of Capitalists

There is a conclusion that follows from all this which will appear highly paradoxical to many people, because

it totally contradicts all they have been mistakenly led to believe—by the educational system, by the media, and by our culture in general—but which is nonetheless perfectly logical and correct. That is, *the more the private property rights of capitalists are respected, the greater are the benefits to noncapitalists*. Because to the extent that their rights are respected, the capitalists are encouraged to save and accumulate capital; their own consumption is small in relation to their capital and grows only as their capital grows. In each year the demand for labor and for capital goods is correspondingly larger—because of the capitalists' greater saving—and the share of consumers' goods purchased by wage earners is likewise correspondingly larger.

The profound significance of a greater demand for capital goods relative to consumers' goods, which results from the capitalists' security of property and greater saving, for capital accumulation, for the productivity of labor, and thus for real wages will be explained in Chapter 14.⁸ The vital significance of a higher degree of capital intensiveness—that is, a higher ratio of accumulated savings and capital to current consumption expenditure—for the ability to implement technological advances, and thus to raise the productivity of labor and real wages, will be explained in Chapters 14 and 17.⁹

Also, of course, the more the property rights of the capitalists are respected, the more powerfully do the incentives of profit and loss operate to make the capitalists satisfy the demand of the consumers, because the profits of doing so are correspondingly less diluted by taxation. At the same time, the losses of failing to do so are not offset by reduced tax payments on other profits, since, to the extent that the property rights of the capitalists are respected, there are no tax payments on other profits. Thus losses are experienced with their full impact. Nor, when property rights are respected, are losses compensated for by subsidies of any kind. (The existence of subsidies is incompatible with the property rights of those who are forced to pay taxes to provide them.) In addition, respecting the property rights of the capitalists means leaving them legally free to enter any branch of production they wish. Thus it means the freedom of competition and therefore, in this way too, the full effect of profit and loss incentives in bringing about new and improved products and in improving the methods of producing already existing products and thereby continually reducing costs of production and prices.

Respecting the property rights of capitalists also means not imposing on them arbitrary requirements that raise costs of production and thus prices, such as compulsory bargaining with labor unions, zoning laws, government building codes, regulations for alleged product safety, and the regulations imposed by the ecology movement.

All of these regulations are actually at the expense of the consumers, in that anything which raises costs of production ultimately raises prices.¹⁰ Still worse, as I will show in Chapter 14, all governmentally imposed cost increases and the inefficiencies they represent have a cumulative negative effect on the ability to accumulate capital and thus to raise the productivity of labor and real wages.¹¹

But what is most important of all in the long run, and subsumes all the other benefits, is that if the capitalists' property rights are sufficiently respected, then from year to year *the total production of consumers' goods available to everyone tends to grow and thus the purchasing power of everyone's income tends to rise*. In other words, there is not only a general benefit from private ownership of the means of production, but a *progressively increasing general benefit*. This should be obvious merely on the basis of what was shown back in Chapter 6 about the effects of the uniformity-of-profit principle in bringing about economic progress. As indicated, however, later discussion will show how the stimulus to economic progress provided by the uniformity-of-profit principle combines with the saving and productive expenditure of the capitalists to achieve a steadily growing supply of capital goods, a rising productivity of labor, and thus rising real wage rates, and that this progress is the more rapid, the more the property rights of the capitalists are respected.¹²

The conclusion should already be obvious that an individual is far better off as a nonowner of the means of production under capitalism than he is as an equal owner under socialism. For in his capacity both as a wage earner and as a consumer he obtains the benefit of the means of production owned by others. In a division-of-labor, capitalist society, others' means of production are the source both of the demand for his labor and of the supply of the goods he buys. And his benefit in both capacities is the greater, indeed, becomes progressively greater, the more the property rights of those others are respected.

Of course, nothing I have said means that under capitalism the mass of people must be nonowners of means of production. It may be that everyone would own some means of production, if not directly, then indirectly, through such forms as stock or bond ownership, ownership of mutual-fund shares, and ownership of life-insurance policies. It is absolutely certain that everyone who chooses to save under capitalism can accumulate a substantial amount of personal savings representing either means of production or such assets as homes financed by means of mortgages. Nevertheless, the fundamental gain of the mass of people comes from means of production owned by others, above all, by large capitalists. This gain is the source of real incomes high enough to make

possible significant saving on the part of the average person.

2. The Capitalists' Special Benefit from Private Ownership of the Means of Production

The preceding section showed the general benefit—the progressively increasing general benefit—that everyone, capitalist and noncapitalist, derives from the institution of private ownership of the means of production in a division-of-labor society.

It is now necessary to consider the *special benefit* derived by the capitalists from their ownership of capital. Obviously, no matter what the gains that their capital provides to noncapitalists, it is better to be a capitalist than a noncapitalist, and better still to be a wealthier capitalist than a poorer capitalist. What needs to be answered now is the question of what precisely is the nature of these special gains that the capitalists derive from their capital that is over and above the gains that everyone else derives from it.

There is undoubtedly a temptation to answer that the capitalists earn profits or interest on their capital, which the rest of society does not, and that that is their special benefit. This answer is mistaken. It is true that only the capitalists earn the profits and interest on their capital. However, to the extent that they save and invest their profits and interest, the profits and interest provide the same kind of general benefit as their original capital—that is, the saved profits and interest represent additional means of production serving the general buying public and are the source of additional wage payments. Thus, the profits and interest that the capitalists earn are actually *not* the measure of the special benefits they derive from their ownership of the means of production.

There are two gains that the capitalists obtain which others do not. The first is the portion of their profits and interest that they do not save and invest, but *consume*. Even this overstates their special gains to the extent that their consumption includes such things as the support of universities, libraries, hospitals, and opera companies, because here again are general benefits. The second is the *psychological value* that the possession of capital has. To the extent that an individual possesses capital, he has the potential of consuming it. He thus has the psychological security of knowing that he could consume it if he had to or wanted to.

Now so long as the institution of private ownership of the means of production remains secure, this advantage of owning capital usually remains strictly psychological. That is to say, the potential the capitalists have of consuming their capital usually remains just that—a potential. The capital itself is generally not consumed, but left

invested; and upon death, it is passed to heirs.

In part, this is because capitalists who are in business regard the possession of their capital as essential to their livelihood. Significant-sized capitalists, moreover, whether they are in business or not, are likely to regard the possession of their capital as being the means by which they can live for the remainder of their lives and provide for their children and grandchildren. (In today's conditions, significant-sized capitalists can be taken to mean those with a capital of, say, \$2 million or more.) As a result of these facts, the major instances in which the consumption of capital occurs is when the rate of profit or interest that is earned falls to the point that it cannot provide the standard of living the capitalists feel they can afford on the basis of their accumulated capital.¹³ In such circumstances, they encroach upon their capital. Even then, they generally do so only to a relatively modest degree, because they require the great bulk of their capital as the means of providing for their future needs and wants.¹⁴

On the basis of this and previous discussion, it should be clear that if the institution of private ownership of the means of production is secure, the *actual* consumption of businessmen and capitalists, whether out of current profits or interest or out of capital accumulated out of past profits or interest, is minor in comparison with wages and the consumption of wage earners. This is especially true of the consumption of the significant-sized businessmen and capitalists, who own the great bulk of the capital of the economic system and earn most of the profits and interest in the economic system. In fact, in a country with the degree of security of property that was historically enjoyed in the United States, the consumption of the significant-sized businessmen and capitalists, including whatever great mansions and ocean-going yachts and caviar and champagne they might consume, would most likely amount to not much more than about 10 percent of the total consumption taking place in the economic system. This is because the mansions and yachts, and the suppers of caviar and champagne, in their hundreds and thousands pale into insignificance alongside the consumption of wage and salary earners in their tens of millions enjoying ordinary houses and automobiles and even just hamburgers and Coca Cola.¹⁵

Implications for Redistributionism

The above facts about the capitalists' special benefit from the institution of private ownership of the means of production have an important bearing on the appraisal of demands for the redistribution of wealth and income, and for socialism, insofar as socialism is advocated as a method of redistribution. For after all is said and done, it is something on the order of a mere 10 percent of the

overall, total consumption of the economic system that turns out to be the grand prize for which the redistributors and socialists have been clamoring all these years! *This* is the great fund of wealth by means of which they have expected to abolish all poverty, cure disease, and achieve utopia; and for the sake of which they have been ready to overturn existing society, seize private property, and shed rivers of blood—all in magnificent obliviousness to the fact that capitalism itself gratuitously provides such wealth *over and over again every few years*, through economic progress and an accompanying 2 or 3 percent annual rate of improvement in the productivity of labor. Indeed, if the approximately 10 percent of total consumption that is accounted for by the consumption of the significant-sized capitalists is divided by the approximately 90 percent of consumption that already takes place on the part of the rest of the population, the resulting 11 percent ratio would be made good for rest of the population over and over again approximately every four to five years, through economic progress.¹⁶

These points need to be emphasized, in order to understand the actual nature of the demands for redistribution and socialism. The conclusion that follows from them is that even if the redistributors and socialists could succeed in expropriating the capitalists' wealth without causing the destruction of that wealth or of its productivity—which, of course, they cannot—the utmost that they could obtain for the benefit of the average person that he would not already have *is his share of the approximately 10 percent of total consumption that is accounted for by the consumption of the significant-sized capitalists*. And this, of course, would be a one-time-only, nonrepeatable benefit. This would be the limit of the "benefit," because anything beyond it would represent capital decumulation.¹⁷

Obviously, even if it could be obtained, such a benefit would not be worth making into the leading objective of a political philosophy and movement, let alone fighting a revolution for. But the fact is, of course, that no such benefit can be obtained. The attempt to seize the 10 percent can only inflict injury on those intended to benefit from the seizure. It must deprive them both of all the vastly greater future gains they would have had from the further operation of capitalism, and of the continued enjoyment of the gains they have already obtained from the operation of capitalism up to that time. For the capitalists cannot be forcibly prevented from consuming without losing interest in the management of their capital, and in its accumulation in the first place. Their capital is valuable to them only insofar as it serves as a source of actual or potential consumption for them or their heirs. To the extent that their ability to consume is forcibly restricted, the value of their capital to them is destroyed.

For example, a forced limitation of a capitalist's consumption to some fixed amount, such as \$50,000 per year, would make all that portion of his capital valueless to him that was beyond what was required to provide the income needed for such consumption. If, for example, he had \$5 million of capital and the rate of return on capital were 5 percent, so that \$1 million of capital was sufficient to provide the income needed for the maximum permitted consumption, he could well lose interest in the management of \$4 million of his capital, and in the accumulation of such capital in the first place. For the \$4 million would arguably no longer be able to contribute anything to his life and well-being. Indeed, even if for reasons of financial security he always wished to possess capital equal to some definite greater multiple of his annual consumption than implied by the assumed 5 percent rate of return, such as 40 times his maximum permitted annual consumption of \$50,000, he would have no motive to be interested in possessing any capital beyond \$2 million in this case, and thus would still lose interest in the management of the other \$3 million of his assumed capital, and in the accumulation of such capital in the first place.

All efforts to limit the consumption of capitalists must result in the destruction of incentives to accumulate and maintain capital. If the limits were set very high, at a level of consumption that the great majority of capitalists could never expect to reach, the effect would be to destroy the incentives of the most successful capitalists. As the limits were lowered, the effect would be to destroy the incentives of more and more capitalists. Whatever the level of interference, any possible per capita gains to the general public from obtaining funds the capitalists otherwise would have consumed must be far more than offset through declines in the incentive to improve and even maintain production. If, for example, the public attempts to reap the gains of limiting a capitalist's consumption to, say, \$50 million a year, so that only a bare handful of capitalists is affected, namely, multibillionaires, the possible gains to the treasury are absolutely minimal, while the losses in terms of innovation and the growth of major new industries are substantial. If the effort is made to capture any substantial part of the capitalists' overall consumption, the disincentives to capital accumulation and the management and maintenance of capital are such that the socialization of the means of production would have to follow as a logical next step. Because in the absence of capitalists caring about their capital, the only party left to care would be the state. But, of course, for the reasons explained in the last chapter, socialism would also mean the collapse of production.

Essentially similar reasoning applies to proposals to limit the after-tax income of capitalists to some fixed amount, such as was advocated earlier in this century by

Eleanor Roosevelt and the labor union leader Walter Reuther. The enactment of such a proposal would first be accompanied by a decumulation of capital, to the extent that the capitalists considered their existing capital sufficient to enable them to consume in excess of their statutorily limited income. For example, a limitation of after-tax income to \$50,000 a year would not stop capitalists from consuming in excess of \$50,000 a year so long as they judged their capital to be sufficient to provide such consumption. In the words of von Mises, "If one eliminates the capitalist's role as receiver of interest [profit], one replaces it by the capitalist's role of consumer of capital."¹⁸ Such a limitation of income would obviously have to be followed by a limitation of the capitalists' consumption and then, for the reasons just explained, by the government taking over the management of their capital as well.

The destructiveness of redistributionism is evident in the decline of the American economic system that has taken place in recent decades. The redistributors have succeeded in depriving the significant-sized capitalists of perhaps as much as half of what they would otherwise have consumed, and the American economic system of perhaps as much as half of the capital that such capitalists would otherwise have accumulated and used to the advantage of everyone. This conclusion is supported by the fact that in the nineteenth century and the first few decades of the twentieth century, the ratio of total accumulated capital in the United States to the so-called national income of the United States (*viz.*, the sum of all wages and salaries and profits and interest earned in the country), was on the order of five or six to one. However, as the redistributors gained ground in imposing and expanding the welfare state and enacting policies of confiscatory taxation, government budget deficits, and inflation to pay for it—all of which policies undermine the ability to accumulate capital—this ratio, which is typically called the capital-output ratio, has fallen to three to one.¹⁹

The reduction in the ratio of capital to national income represents a reduction in the overall degree of capital intensiveness of the American economic system.²⁰ As I will explain in Chapters 14 and 17, reduction in the degree of capital intensiveness signifies a reduced ability to implement technological advances.²¹ A second, closely related result that redistributionism has caused and that operates against economic progress, is a reduced demand for capital goods relative to the demand for consumers' goods. This is the necessary consequence of taxing away funds that would otherwise have been saved and productively expended, that is, expended for business purposes, and using those funds instead to finance consumption expenditures by the government or those to whom the

government gives money. The reduction in the demand for capital goods relative to the demand for consumers' goods causes a reduction in the production of capital goods relative to the production of consumers' goods. It thereby reduces the ability of the economic system to increase or even to maintain its supply of capital goods.²²

These destructive results stand alongside of and reinforce the destructive results of redistributionism that can be understood in the light of the uniformity-of-profit principle, namely, the effects of depriving businessmen of the financial incentives and means that the freedom to earn and keep the profit one earns provides for improving and expanding production. Thus, it should not be at all surprising that as a result of the destructiveness of redistributionism, the economic system of the United States is now stagnating. In effect, for the sake of denying wealthy capitalists a portion of their luxuries—for the sake of depriving them of an amount of consumption equal perhaps to 5 percent of the total consumption of the economic system—the average American wage earner has been deprived of the benefits of economic progress and the annual improvement in his standard of living, which would have added up to far more than that 5 percent within a very few years and would have done so over and over again. Further substantial implementation of redistributionism will almost certainly result in an annual rate of decline in the standard of living of the average American wage earner.

The destructive effects of redistributionism on capital accumulation have been evident all along in the very size of what the redistributors have expected to accomplish and have believed to be available as the means of accomplishing it. As they have depicted matters, what is available for raising the standard of living of the masses is not the small percentage of the output of consumers' goods that the capitalists personally consume, *but the whole of the capitalists' existing wealth*. The propaganda of the redistributors and socialists has always depicted the capitalists as rich fat men, whose larders are overflowing, while the plates of the poor are empty. It has demanded that the capitalists' wealth be shared for purposes of mass *consumption*. Since, in reality, the wealth of the capitalists is overwhelmingly in the form of factories and other capital goods, this has all along been a blatant demand for capital decumulation. The poor are to be benefitted by consuming the capital that underlies the productivity of labor and the payment of wages, and without which production must plunge. Thus, practically on its face, redistributionism has been a policy of destruction.

It is important to bear in mind that no undue emphasis should be placed on the consumption of the capitalists

constituting any definite percentage of total consumption at any definite time, such as 10 percent. The essential point is that their consumption will be the smaller, and their saving and demand for labor and capital goods the greater, the more fully are their property rights respected and secure. This is what in the long run guarantees the highest possible percentage of consumption stemming from wages and the lowest possible percentage stemming from profits and interest. Thus, if at some point it were found that the consumption of the capitalists relative to that of wage earners were far higher than what I have indicated, it would not at all follow that any kind of case for redistributionism then existed. On the contrary, such a situation would almost certainly largely be the result precisely of the threat of redistribution. The remedy would be the abandonment of all such threats and the establishment of the security of property. Then, a greatly intensified process of competition in saving would take place among the capitalists, in which those who consumed the least and saved the most came to own an ever increasing portion of the capital of the economic system and more and more determined the consumption and saving of all capitalists taken together.²³

I have already demonstrated the destructiveness of redistributionism insofar as it is a demand for the socialization of the economic system. Its destructiveness will become further evident as we consider the lesser measures that the redistributors have advocated for implementing their program: namely, government ownership of isolated industries and the progressive taxation of incomes and inheritances, and, in non-division-of-labor societies, land reform. In the discussion immediately following, we will consider government ownership of isolated industries.²⁴

Destructive Consequences of Government Ownership

The government's ownership of a business supposedly makes every citizen an equal owner of that business, and in this way supposedly benefits him. Thus, every American is supposed to be an approximately one 260-millionth owner of the U.S. Postal Service, Amtrak, the national parks, and so on.

Yet, one need hardly do more than name such examples, in order to understand the destructiveness of government ownership. The citizen's share in government enterprises does him no good whatever. The fact that the enterprise is government owned merely means that it is operated without benefit of profit-and-loss incentives and the freedoms of individual initiative and competition.²⁵ The result is almost always gross inefficiency, high costs, poor service, and low quality of products. In fact, in one major case—the government's ownership of enormous areas of the Western states and of Alaska—the

effect of government ownership is largely to deprive the citizen of all possible economic benefit from the existence of the property. For much of the property is set aside as "wildlife preserves" and "wilderness areas," and its economic development is either totally prohibited or made extremely difficult and severely limited.

The average American is far better and more economically served by the privately owned telephone companies and airlines than he is by the U.S. Postal Service, Amtrak, and all the various municipally owned subway and bus lines. He is much better off dealing with them, even if he does not own a single share of their stock, than in dealing with the government enterprises, which are supposed to be his. For in dealing with the private enterprises, he obtains not only the benefit of the existence of their capital, but also the benefit of the employment of their capital *under the incentives of profit and loss and the freedoms of individual initiative and competition*, with the result that they are highly motivated to serve him and to serve him progressively better.

The adverse consequences of government ownership are, of course, enormously compounded when it goes beyond the case of isolated industries to embrace the entire economic system. Then, in addition to the far more serious problems created directly by the lack of profit-and-loss incentives and the freedoms of individual initiative and competition, there are the problems created by the destruction of the price system, which, as we saw in the last chapter, means the disintegration of the economic system into chaos.

Putting aside for the moment the consequences of a socialized economic system, as opposed to isolated socialized industries, it is worth noting that government ownership does not normally provide the alleged citizen-owners with any of the *special benefits* of ownership that exist under private ownership of the means of production. Government ownership does not give the alleged citizen-owner the psychological security that the possession of capital gives to a capitalist. Because, unlike the capitalist, *he cannot sell his share in a government enterprise*. He is born with his share and must die with it. *Nor*—except in the most unusual cases—*does he receive dividends on his share*. In no sense does his alleged ownership provide him with any actual or potential means for consuming and thus for enriching his life. Thus, in no way does it provide him with the distinctive benefits that private ownership of the means of production bestows.²⁶

In the case of government ownership of industry, the citizen's share not only normally brings him none of the special gains of ownership, but, on the contrary, is almost always a *liability* to him, in that government enterprises almost inevitably incur deficits, which he, the average citizen must make good through his taxes. Government-

owned enterprises incur deficits precisely because it is the taxpayers who must make them good, under coercion. The administrators of the enterprises do not suffer any losses out of their own pockets, nor are they appointed or removable by those who do suffer the losses—the taxpayers. At best, they are appointed and removable by elected officials. When it becomes one of the powers of government to own and operate business enterprises, these officials owe their election and their prospects for reelection to promises to favor some groups at the expense of other groups—namely, large and vocal groups at the expense of small and quiet groups. The individual taxpayer is smaller and quieter than any group, and thus he ends up as the principal victim of pressure-group warfare. The politicians and the bureaucrats they appoint are free to use the government enterprises to provide costly vote-buying “services” and to have them operate with inefficient methods of production, which also buys votes by providing lucrative contracts or employment for pressure-group members; and he, the taxpayer, must keep still and simply cover the losses.²⁷

Thus, the average citizen is a loser in his dealings with government enterprises not only in his capacity as a consumer, but also, however ironically, in his capacity *as an owner*—in the very capacity in which he was above all supposed to benefit. He is a loser both ways. And, of course, the magnitude of his loss grows exponentially as the economic system approaches full socialization.

Government ownership is sometimes supported on the grounds that it keeps the use of property free, whereas private ownership would result in the imposition of charges. This argument comes up most clearly in such cases as government ownership of beaches and parks, but it is present in the support for government ownership of every kind. And, indeed, the case for government ownership in such instances is about as valid as would be an argument for government ownership of all other land based on such considerations. Thus, one might argue that if the government socialized all land, people could obtain food without having to pay for it. They would merely have to go into the forest and collect the nuts and berries that grew there, without having to pay anyone for the right to do so.²⁸ Of course, there would be nothing to eat but nuts and berries and no more of them than nature provided, with the result that most people would die of starvation.

In contrast, when the land becomes private property, the owners collect charges for its use, or for the products of its use. But those charges serve merely to make it worthwhile for the owners to apply their intelligence and labor to the improvement of their property, with the result that yields progressively improve and increase. Thus the

payment of charges results in progressively growing supplies that continually raise the standard of living of those who pay them. Exactly the same is the case with beaches and parks. Private ownership would entail charges, but it would also be the foundation of progressive improvement in the benefits derived from the existence of beaches and parklands, because the charges would serve to introduce the incentives of profit and loss and the phenomena of individual initiative and competition. That is, it would serve to bring about the application of human intelligence and the progressive improvement that the use of intelligence makes possible. As a result, instead of the nonowners paying no charges and obtaining little more than nothing, they would pay something and obtain more and more.²⁹

Profit Management Versus Bureaucratic Management

A major factor bearing on the superiority of privately owned enterprises over government-owned enterprises is the fact that the former are characterized by what von Mises calls *profit management*, while the latter are characterized by what he calls *bureaucratic management*. In the absence of government interference, the ability to construct separate balance sheets and income statements for the constituent parts of an enterprise makes it possible for private enterprises to delegate substantial authority to subordinate managers, such as branch and division managers. Because their activities can be appraised on the basis of their separate profit-and-loss performance, such subordinate managers can be allowed to exercise major discretion within the framework of the one, overall guiding business directive which is simply to make profits and avoid losses. What is of the greatest importance, is that they can be given discretion in the spending of money, which they can be trusted to spend wisely, because they have a powerful incentive to hold down costs in order to show a greater profit on the operations for which they are responsible. In effect, such managers are made junior partners, which thereby extends throughout the firm not only the incentives provided by private ownership of the means of production but also a corollary freedom of individual initiative.³⁰

In contrast, *bureaucratic management* necessarily characterizes government-owned enterprises, owing to the inherent lack of profit-and-loss incentives at their very base, which incentives can be provided only by private ownership. Such enterprises—for example, a police department—very often do not and cannot sell their products, which by itself makes the construction of any kind of income statements for subordinate units out of the question. And even where they can sell their products, as in the case of a post office, the lack of profit-and-loss incentives at the very base of their operations rules out

any form of profit management at subordinate levels. Thus, government enterprises must be conducted bureaucratically—that is, in accordance with detailed rules and regulations rigidly prescribing every procedure and leaving virtually nothing to the discretion of the officials, who otherwise would have no reason to limit expenditures.³¹ Indeed, when one considers that government is always the agency that resorts to the use of physical force against people, and that spends public funds obtained by taxes, the bureaucratic restriction of the discretion of its officials appears positively desirable. Bureaucratic management is actually the form of management that is *appropriate* to the conduct of government affairs.³²

The appropriateness of bureaucracy to government is an argument for the strict limitation of the functions of government, and thus the confinement of bureaucratic management to the sphere in which it is necessary to restrict the use of physical force. When the functions of government are not thus limited, bureaucratic management spreads to private enterprise. For then government interference undermines the strength of profit-and-loss incentives, makes business firms dependent on the decisions of government bureaus, and forces them to employ former bureaucrats in leading positions in order to be able to deal with the government bureaus.³³

Thus, business firms become less and less subject to the power of profit-and-loss incentives and more and more come to resemble the bureaus that determine their fate. For example, under affirmative-action laws and environmental-protection laws, it is out of the question to leave anything to the discretion of lower-level business managers, lest the well-being of the whole firm be jeopardized by the inadvertent violation of some government regulation. Under such conditions, the lower-level business managers must be as careful to “go by the book” as any government bureaucrat.³⁴

The “Successful” Nationalizations of Oil Deposits: A Rebuttal

The leading exceptions to the principle that the citizen loses even in his capacity as an owner of government enterprises occur when such an enterprise has the good fortune to own low-cost mineral deposits and at the same time enjoys substantial monopoly privileges in selling outside the country. This is the position of the nationalized oil industries in various Arab countries.

These industries were established and developed by private oil companies, who continue to play a major role in their operation. Their success is principally the result of the fact that the government of the United States has granted them extensive monopoly privileges in the world market by severely hampering the activities of their major competitors—namely, the American producers of

oil and other forms of energy—in all the ways I explained in Chapter 7.³⁵ In the absence of these measures by the U.S. government, the price of oil would not have risen any more than most other prices, and the inefficiencies of government ownership would have prevented the Arab countries from earning any very great profits, despite the high quality of their oil reserves. Further progress in the production of energy in a free United States would eventually have inflicted losses on such inefficiently run outfits.

As matters stand, the free telephones, free medical care, and so on, that the citizens of Kuwait, say, are able to enjoy, thanks to the dividends their government pays from its oil profits, and the lesser benefits that the citizens of other thinly populated Arab countries obtain—all this is paid for at the expense of the impoverishment of everyone else in the world who must pay the artificially enhanced price of oil. Scores of millions of people in the non-oil-producing countries are that much closer to starvation and death because the oil industries of the Arab countries are nationalized and enjoy monopoly privileges.

To summarize much of our discussion in this section: What we have seen is, first of all, that insofar as the capitalists’ special benefit from the ownership of the means of production takes the form of an enhanced consumption, it is quite small in relation to the size of overall consumption, and thus that nothing of great significance could be gained by the average person from its seizure, even if it were possible to seize it. And then we have seen that the attempt to seize it must backfire in a radical decline in production and the overall volume of goods available, because the capitalists’ incentive to accumulate and maintain their capitals would be destroyed and the ensuing socialization of the economic system would also cause collapse. We have seen that redistributionism is destructive practically on its face, in that it is a call for the wholesale consumption of the capitalists’ capital, and we have seen its destructive role in the present economic stagnation of the United States. And, finally, we have seen that the socialization of isolated industries causes losses to the average person both in his capacity as a buyer of the products of the socialized industries and in his capacity as an alleged owner of the socialized industries. That is, we have seen that in addition to depriving the buyers of the benefits of profit-and-loss incentives and the freedoms of individual initiative and competition in the industries’ operation, socialization also fails to deliver the special benefits of ownership that exist under capitalism. This is the case inasmuch as the citizen cannot sell his alleged shares, and, instead of receiving dividends, almost always ends up paying higher taxes to cover the socialized enterprises’ losses. We have

also seen that the socialization of business, and growing government interference, are responsible for the bureaucratization of business, even of business that still remains privately owned.

3. The General Benefit from the Institution of Inheritance

It is necessary to consider the benefits of two particular forms of the institution of private property and private ownership of the means of production which have come under special attack, namely, the institution of inheritance and, in Section 5, the private ownership of land. These institutions are denounced even by people who in other respects consider themselves supporters of private property and private ownership of the means of production.

As in the case of the broader institution of private property and private ownership of the means of production as such, the institution of inheritance is perceived as being of benefit only to the owners of the property involved—in this case, those who are fortunate enough to be heirs—and not as being of benefit to anyone else. Indeed, the interests of the nonheirs are usually perceived as lying with the confiscation and redistribution of inheritances, and thus with the more or less complete abolition of the institution.

Despite the popularity of this view, the fact is that in a division-of-labor society, substantial inheritances are overwhelmingly in the form of means of production, precisely because the far greater part of the wealth of the bequestors—capitalists—is in the form of means of production. If such inherited wealth remains invested—and it almost always does when it is received in a large amount—its existence is to the benefit of everyone. In order to benefit from its existence, one need not be an heir; one need merely be a buyer of the products it helps to produce and whose supply is increased because of it. One need merely be a wage earner, whose labor is in additional demand and whose wages are higher because of it.

The institution of inheritance powerfully promotes the accumulation of capital. It provides a motive to people to maintain their capital, and even to go on accumulating additional capital, as long as they live—for the sake of their heirs. Its effect is that substantially more capital exists than would exist without it. Everyone in a division-of-labor society benefits from the existence of this additional capital, whether he himself is an heir or not. He benefits both in his capacity as a buyer of products and in his capacity as a wage earner. He benefits in the former capacity because the generation of additional capital raises and goes on raising the productivity

of labor and thus the supply of goods available for all to buy. He benefits in the latter capacity because, at the same time, it increases the share of total consumption that is enjoyed by wage earners in comparison with nonwage earners. Rational self-interest dictates that everyone, nonheirs as well as heirs, uphold the institution of inheritance. From the point of view of the nonheirs, the rationale is that it enables their employers to pay them more and their suppliers to supply them with more, and, indeed, to supply them progressively better—at prices that are lower and lower relative to the wages they earn. This last is the effect of the greater relative demand for and production of capital goods and the higher degree of capital intensiveness that the institution of inheritance achieves.³⁶

As previously pointed out, however startling it may seem, the simple fact is that in a division-of-labor society one benefits from the property of others when those others are one's employers or suppliers, because the effect of their property is a greater means of buying what one sells and of producing what one buys. The institution of inheritance enhances these sources of gain.

Indeed, the preceding observations have somewhat understated the case for the institution of inheritance from the point of view of the nonheirs. While it is true that most large inheritances do remain invested, the institution of inheritance promotes capital accumulation even in the cases in which the heirs consume some or all of what they receive—as an elderly widow or minor children must often do, or as spendthrift heirs simply choose to do. For even in these cases, the capital is first accumulated, and because estates are constantly being built to be left to heirs, there is *permanently* more capital. Even in these cases, in which all or most of an inheritance is consumed by the heirs, there is the capital that exists in the inheritance “pipeline,” so to speak, and which would not exist in the absence of the institution of inheritance.

It is necessary to realize that inherited wealth can easily be lost through unwise investments on the part of the heirs. In a division-of-labor society, wealth is never invested just once, for all time; it must constantly be reinvested, under ever-changing conditions. Materials and labor services are fully used up in the production of a single batch of products and must be replaced immediately thereafter if production is to continue. Machinery and factory buildings, while much longer lasting, are also constantly in process of wearing out; they too must be periodically replaced. On the other hand, as time goes on, new products and new methods of production are introduced and all those other dynamic changes occur that take place in connection with economic competition. These changes make it impossible for the heirs to con-

tinue with a routine established by the parent or grandparent who built their fortune. They must constantly *reacquire* their wealth through their own successful investments, investments which must win the approbation of the buyers of the products concerned, under the freedom of competition.

To the extent the heirs lack the ability to make the right investment decisions, but nonetheless attempt actively to manage their funds themselves, they risk the loss of their entire fortune. If they recognize their lack of business ability, or if it has been recognized for them by the bequestors of their wealth, they must be content with a sharply reduced rate of return on their capital, which is the necessary accompaniment of making investments recognized as having a high degree of safety of principal. And from that low rate of return must usually be deducted management or trustees' fees.

The effect of these facts is that unless one or more of the heirs possesses extraordinary ability, the relative significance of any given fortune in the economic system tends steadily to diminish as time goes on. For even if the heirs do not lose it outright through poor investments, and even if they are content to live within the income afforded by the low rate of return they earn on their capital, their fortune is unable to grow in pace with the new capital being accumulated by more-talented investors earning higher rates of return and therefore able to save and accumulate capital more rapidly. Moreover, the significance of any given fortune is further diminished by a tendency toward its constant subdivision among a growing number of descendants, as one generation succeeds another.

In just this way, the wealth of the present-day Astors and Vanderbilts, once among the greatest fortunes in the country, is now not nearly so large in relation to the rest of the American economic system; and that of any given individual Astor or Vanderbilt is no greater than what hundreds of thousands of individuals have accumulated purely by their own efforts, all within the present generation. Even the much more recent and initially much greater fortunes of the Rockefellers, Fords, and Mellons show the same tendencies toward decline in their relative significance.

The Destructive Consequences of Inheritance Taxes

The inheritance tax, especially on large inheritances, where it is often confiscatory, is practically a pure tax on capital. To the extent it exists and is actually carried out—that is, to the extent the so-called loopholes are closed, so that the tax cannot be avoided—the long-run effect is to reduce the accumulation of capital by reducing the building of estates in the first place. It is pointless for people to accumulate fortunes, intended to be be-

queathed to heirs, which, upon their death, the government confiscates and prevents from reaching the heirs. The effect of confiscatory inheritance taxes is to cause the builders of estates to consume their income more heavily and not to bother earning part of the income they might otherwise be capable of earning at any given time. For their motivation both to save and to earn the income out of which saving can occur is reduced.

Inheritance taxes which are not so high as to prevent heirs from substantially benefitting from the accumulation of estates do not deprive the builders of estates of the motive to earn and save. By the same token, they do not achieve the egalitarian objectives of the supporters of the inheritance tax. Nevertheless, even these more-modest inheritance taxes reduce capital accumulation to the extent that they are paid with funds that otherwise would have remained invested. Any inheritance tax whatever reduces capital to the extent that it is paid with funds that otherwise would have remained invested.

The specific way that this occurs is that the heirs or the executors of estates find it necessary to sell part of the estate to pay the taxes. This siphons funds from the buyers of these portions of the estates into the government's treasury. If the heirs had not had to sell, the buyers of these portions of the estates would have had to use their funds essentially for the purchase of new capital assets, which would have existed alongside of and in addition to the inherited wealth of the heirs. Instead, as matters stand, the funds of the buyers are diverted from the purchase of such additional capital assets into the purchase of part of the heirs' existing capital assets, and from there to the government's treasury and its expenditures. The result is less accumulated capital.

This remains the result even if the government were to use the proceeds of the inheritance tax exclusively for such alleged capital purposes as the building of roads, bridges, canals, and tunnels, the making of river and harbor improvements, and the like. For even if government expenditures for such purposes really did represent capital formation, which they do not, they would be at the expense of that much less private capital formation, so long as they were financed by the inheritance tax.³⁷

The fact is, however, that most government spending is avowedly for purposes of consumption—such as welfare payments and expenditures for military preparations. And what is for alleged capital purposes is almost always carried out with enormous waste and inefficiency in comparison with what private enterprise would achieve if it were responsible for the same undertaking.

Thus, when they do the least damage conceivable, inheritance taxes represent a diversion of capital into financing activities that are necessary or useful to a country's ability to produce, but which are carried on

inefficiently under government ownership. Such activities should not be carried on by the government in the first place; if they are carried on by the government, they should not be financed by an inheritance tax or by any other tax that significantly reduces capital accumulation. Finally, the use of the inheritance tax to finance such expenditures as welfare payments and outlays for defense, which is what, for the most part, it is actually used for, is nothing but an unmitigated assault on the foundations of a country's standard of living.

In every case, an inheritance tax reduces the demand for labor that business firms are able to make and thus either the wage rates or volume of employment that they are able to offer. Simultaneously, it reduces the economic system's overall degree of capital intensiveness, and thus its ability to implement technological advances.³⁸ Equally important, it reduces the demand for capital goods relative to the demand for consumers' goods and thus the economic system's degree of concentration on the production of capital goods, and, consequently, the ability of the economic system progressively to raise the productivity of labor and real wages.³⁹ An inheritance tax always represents a diversion of funds from capital to consumption and is thus a force working against both economic progress and the share of total consumption in the economic system that goes to the employees of business firms, whose wages are paid out of capital.⁴⁰ Thus, inheritance taxes are against the interests of everyone, nonheirs as well as heirs.

4. The General Benefit from Reducing Taxes on the "Rich"

The progressive personal income tax, the corporate income tax, and the capital gains tax all operate in essentially the same way as the inheritance tax. They are all paid with funds that otherwise would have been saved and invested. All of them reduce the demand for labor by business firms in comparison with what it would otherwise have been, and thus either the wage rates or the volume of employment that business firms can offer. For they deprive business firms of the funds with which to pay wages.

By the same token, they deprive business firms of the funds with which to buy capital goods. This, together with the greater spending for consumers' goods emanating from the government, as it spends the tax proceeds, causes the production of capital goods to drop relative to the production of consumers' goods. In addition, of course, they all operate to reduce the degree of capital intensiveness in the economic system and thus its ability to implement technological advances.⁴¹ The individual and corporate income taxes, and the capital gains tax, of

course, also powerfully reduce the incentive to introduce new products and improve methods of production. In all these ways, as will be shown at length in Chapters 14 and 17, these taxes, along with the inheritance tax, undermine capital accumulation and the rise in the productivity of labor and real wages, and thus the standard of living of everyone, not just of those on whom the taxes are levied.

What makes it difficult for people to recognize the fact that everyone would benefit from reductions, or, better still, the total abolition of all of these taxes on the so-called rich—made possible, of course, by equivalent reductions in government spending—is not only massive ignorance of economics, especially of the general benefit from private ownership of the means of production, but also collectivistic habits of thought inspired by Marxism and its doctrine of class interest. By this last, I mean that when it comes to matters of economics, most people tend to think of themselves essentially as members of the class of wage earners rather than as separate individual wage earners, and to think of their interests as indistinguishable from the interests of other wage earners.

Thus, an individual wage or salary earner knows that he would certainly be better off if his own taxes were reduced by some given amount than if the taxes of a millionaire or some large corporation were reduced by that same amount. As far as it relates just to himself, that conviction is absolutely correct. I, for example, would be much better off if my taxes were reduced by, say, a thousand dollars a year than if the taxes of some contemporary John D. Rockefeller or the taxes of General Motors were reduced by a thousand dollars a year. Where most wage earners go wrong is in generalizing from what is true of a reduction in their own, individual taxes, in comparison with an equal reduction in the taxes of businessmen and capitalists—the "rich"—to conclusions about the effects on them of reducing the taxes of *other* wage earners, in comparison with the same amount of reduction in taxes on businessmen and capitalists.

In considering, for example, whether the taxes of businessmen and capitalists as a class should be reduced by some massive sum, such as \$100 billion, or whether the taxes of wage earners as a class should be reduced by that sum, almost everyone mistakenly assumes that the interest of the individual wage earner lies with the tax reduction going to the wage earners, as though all wage earners shared a common class interest against all capitalists. This, however, is a fallacy, which becomes apparent as soon as one objectively analyses the situation from the perspective of the individual wage earner. Then it becomes clear that much more is involved than the matter of a reduction in the taxes of the rich or an equal reduction in the individual wage earner's own taxes. For example, while it is certainly true that I gain more from my own

taxes being cut by \$1,000 rather than the taxes of a Henry Ford or a Bill Gates, it is absolutely false to believe that I gain more from the taxes of my random fellow wage earners—call them Henry Smiths and Bill Joneses—being cut by \$1,000 each rather than the taxes of Ford and Gates being cut by \$1,000 each.

What is actually involved in the question of a reduction in taxes on businessmen and capitalists as a class in the amount of \$100 billion, versus an equal reduction in the taxes of wage earners as a class, is two separate, further questions, that represent constituent elements of this question. There is first the question of the benefit to an individual wage earner of his own taxes being cut by \$1,000, versus the taxes of any businessman or capitalist being cut by \$1,000. We know the answer to this question: it is more to the individual wage earner's interest that his own taxes be cut. But then there is a second question. Namely, which is more to an individual wage earner's self-interest: a reduction in the taxes of businessmen and capitalists in the remaining amount of \$99,999,999,000, or a reduction in the taxes of wage earners other than himself in the same remaining amount, that is, of 99,999,999 other individuals very much like himself perhaps, but not himself, each getting a reduction of \$1,000?

In other words, put aside the question of a cut in the individual wage earner's own taxes of \$1,000 versus a \$1,000 cut in the taxes of businessmen or capitalists. Consider only the effect on his self-interest of a cut in the taxes of all other wage earners besides himself—all of the Henry Smiths and Bill Joneses of the country—in the combined amount of \$99,999,999,000, versus an equivalent cut in the taxes of businessmen and capitalists—all of the Henry Fords and Bill Gateses of the country. A \$99-billion-plus cut in the taxes of all those other wage earners will make each of them better off, but what will it do for him, for the particular, individual wage earner we are focusing on? To what extent will his fellow wage earners save and invest their tax cut and so raise the demand for his labor? To what extent will his fellow wage earners increase the demand for capital goods and the rate of business innovation and thus bring about improvements in the quantity and quality of the products he buys and thereby increase the buying power of the wages he earns?

It is obvious that the individual wage earner benefits far more from tax reductions on businessmen and capitalists, the so-called rich, than from equivalent tax reductions on his fellow wage earners, and that this is true of each and every individual wage earner, for any wage earner could take the place of the particular individual we have focused on. A tax reduction on businessmen and capitalists will promote capital accumulation, far, far

more than a tax reduction on the mass of the individual wage earner's fellow wage earners. The average businessman and capitalist will save and invest the taxes he no longer has to pay, in far greater proportion than would the average wage earner.⁴² He will be induced to introduce more improvements in products and methods of production, which are also a major cause of capital accumulation, and is a process in which wage earners qua wage earners play little or no role.⁴³ (This is not to say that wage earners are never responsible for innovations. They often are. But as soon as they are, they typically become businessmen. Fundamentally, it is always the prospect of higher profits that stimulates innovations, not the earning of higher wages. It is the prospect of higher profits that leads employers to offer incentives to wage earners to make innovations.) And, on the basis of what has previously been pointed out, the greater saving of the businessmen and capitalists will promote innovation by virtue of making the economic system more capital intensive.⁴⁴ Thus the individual wage earner has far more to gain from the taxes of businessmen and capitalists being reduced than from the taxes of his fellow wage earners being reduced.

The gains from this aspect of the matter are so substantial that they almost certainly outweigh the fact that having them precludes the ability to have the benefit of one's own taxes being reduced by a sum such as a thousand dollars a year. This is merely to say that the gains to an individual wage earner of his own taxes being cut by a sum such as \$1,000 a year are far less than the gains to him of the taxes of businessmen and capitalists being cut by an immensely larger sum such as a \$100 billion a year—that is, by an amount that equals the potential \$1,000 tax cuts of all the millions of *other* wage earners in the economic system, which, in the hands of those fellow wage earners, would have been of little or no value to him.

As I have shown, the individual wage earner gains from cutting the taxes of businessmen and capitalists in part because the effect of their sharply increased saving is significantly to raise the demand for labor and thus, quite possibly, significantly to raise his own wage income.⁴⁵ But far more importantly, the effect of cutting the taxes of businessmen and capitalists rather than of wage earners will be a substantial rise in the demand for capital goods relative to the demand for consumers' goods and a substantial rise in the rate of innovation, including under the latter head, it is worth pointing out, the ability of upstart new firms to grow rapidly and thus to challenge old, established firms.

The effect of this combination is continuing capital accumulation and thus a continually rising productivity of labor. The effect of this, in turn, is a continually

growing supply of consumers' goods relative to the supply of labor, and thus prices of consumers' goods that are progressively lower relative to the wages of labor, which means progressively rising real wage rates, so that in not too many years the average wage earner is far ahead of where he would have been on the strength of a cut in his own taxes.⁴⁶

Starting with tax cuts for the so-called rich—based on equivalent reductions in government spending—is the only hope for the resumption of significant economic progress, indeed, for the avoidance of economic retrogression and growing impoverishment. Because of this, it is actually the quickest and surest road to any major reduction in the tax burden of the average wage earner. It holds out the prospect of the average wage earner being able to double his standard of living in a generation or less. The average standard of living would double in a single generation if economic progress at a rate of just 3 percent a year could be achieved. Such economic progress would also mean a halving of the average wage earner's tax burden in the same period of time—if government spending per capita in real terms were held fixed, for then he would have double the real income out of which to pay his present level of taxes. And then, of course, once all the taxes that most stood in the way of capital accumulation and economic progress were eliminated, further reductions in government spending and taxation could and should take place that would be of corresponding direct benefit to wage earners, that is, show up in the reduction of the taxes paid by them.

Ironically, an aspect of this approach exists in, of all places, Sweden! What has enabled Sweden to have one of the world's highest burdens of taxation and, at the same time, to remain a modern country, more or less advancing, is the fact that the tax burden in Sweden falls far more heavily on the average Swedish wage earner than it does on Swedish business, whose tax burden is actually less than that of business in many other Western countries. (For example, when allowance is made for the fact that Swedish companies can automatically deduct 50 percent of their profits as a tax-free reserve for future investment, the effective corporate income tax rate in Sweden turns out to be below that in the United States: 26 percent versus 34 percent.⁴⁷) If Swedish business had had to bear the burden of taxation borne by Swedish wage earners, the Swedish economy would long since have been in ruins.

This is certainly not to argue for taxation of American workers at a level comparable to the taxation of Swedish workers, or for any increase in the taxes paid by American workers whatever. It is to argue for reductions in government spending sufficient both to eliminate the budget deficit and to make possible substantial tax cuts

on businessmen and capitalists, the so-called rich. It is to argue that as soon as the resulting economic progress begins to increase the real revenues of the government, further tax cuts of the same kind occur, in order further to accelerate economic progress. It is to argue for the achievement first of the total elimination of the inheritance tax, the capital gains tax, the corporate income tax, and the progressive portion of the personal income tax, all taken together, and then, once that has been achieved, for the continuing reduction in the remaining personal income tax, until the personal income tax is totally eliminated. The essential mechanism for achieving these results is a combination of economic progress and continuing reductions in government spending. This is how radically to reduce the taxes of everyone. It is the only way.

Of course, many people will characterize the line of argument I have just given as the "trickle-down theory." There is nothing trickle-down about it. There is only the fact that capital accumulation and economic progress depend on saving and innovation and that these in turn depend on the freedom to make high profits and accumulate great wealth. The only alternative to improvement for all, through economic progress, achieved in this way, is the futile attempt of some men to gain at the expense of others by means of looting and plundering. This, the loot-and-plunder theory, is the alternative advocated by the critics of the misnamed trickle-down theory.

5. Private Ownership of Land and Land Rent

The private ownership of land and natural resources is an aspect of the institution of private property and private ownership of the means of production that has been condemned by economists who in other respects were supporters of capitalism, most notably Henry George. Their case against private ownership of land and natural resources rests on the theory of land "rent" developed by David Ricardo, a theory which, as I will show, is grossly deficient in its failure to incorporate the actual effects of private ownership of land and natural resources. Thus, it is with an exposition of Ricardo's theory of land rent that our discussion must begin.

To understand Ricardo's theory, it is helpful to realize that Ricardo lived in late eighteenth and early nineteenth century England. It was a common practice in the England of that time for farmers to rent the land they worked from aristocratic landowners. Ricardo focused on the portion of such rents that were paid not as compensation for the use of the buildings or any kind of improvements that had been made on the land, but, as he put it, "for the use of the original and indestructible powers of the soil."⁴⁸ This abstract portion of the rents actually paid

and received, Ricardo held, existed even when the land was farmed by its owner. In that case, he maintained, some part of the value of the produce was attributable not as compensation for any cost incurred, nor as a rate of profit on capital invested, but as a payment for the use of the so-called original and indestructible powers of the land itself.

Ricardo explained the origin and determination of land rent in the following way. In a country with an abundance of land of the first quality—that is, best quality—and that is thinly populated, land will yield no rent. In such conditions, people can obtain the best land merely by appropriating it from nature. They are therefore not under the necessity of paying anything for its use. They will pay for the use of buildings or improvements made upon the land, but nothing for the use of the land itself.

Land rent commences, says Ricardo, when the population of the country grows to the point where all land of the first quality has been brought under cultivation, and it becomes necessary to resort to land of the second quality. On land of the second quality, the same quantity of labor and capital produces less than on land of the first quality. It produces less because the soil is simply inferior or because part of the labor and capital must be expended in transporting the produce a greater distance to market or in first making improvements that land of the better quality already possesses naturally.

The rent that will be paid, according to Ricardo, depends on the difference in the productivity of labor and capital on the two grades of land. If, for example, the same labor and capital produce 100 units of product or \$100 of product value on land of the first quality, and only 90 units of product or \$90 of product value on land of the second quality, then people will be willing to pay a rent of 10 units or \$10 for the right to produce on land of the first quality. They will be willing to pay 10 (whether physical units of product or dollars, it is indifferent here) for the use of first-quality land because their labor and capital produce 10 units more on that land than on land of the second quality, which is their next-best alternative. If they can rent land of the first quality for just the smallest amount less than 10, they have a gain in renting it. And thus their competition will drive its rent to 10. At that point, the product or income obtained by labor and capital becomes no greater on land of the first quality than it is on land of the second quality, because rent absorbs the difference.

If the population of the country grows further, to the point where all the land of the second quality has been brought under cultivation and resort must be had to land of the third quality, then, says Ricardo, rent will commence on land of the second quality and will increase on

land of the first quality. For example, if the same labor and capital that produce 100 on land of the first quality, and 90 on land of the second quality, produce 80 on land of the third quality, then when it becomes necessary to resort to land of the third quality, land of the second quality will begin to yield a rent of 10, while the rent on land of the first quality will rise to 20.⁴⁹ Again, the reason is that so long as the rent remains below these amounts, there is an advantage in bidding up the rent, because even after paying it, the same labor and capital will earn more on the first two grades of land than on land of the third quality.

The land-rent theory is intimately bound up with Ricardo's and the other classical economists' ideas on diminishing returns and population growth. The law of diminishing returns held that successive equal doses of labor and capital, when applied to a given piece of land, yield smaller and smaller increments of product.⁵⁰ In effect, having to apply labor and capital to land of the second quality is comparable in its results to the application of a second dose of labor and capital on land of the first quality, and similarly for the extension of cultivation to still lower grades of land.

Ricardo's and the other classical economists' views on population entered in explaining the limits that exist to the formation of land rent at any given time. According to Malthus, whose views on population Ricardo largely accepted, population tends to grow up to the limit of the food supply. Taken in conjunction with the land rent theory, this means that population tends to grow until the land that must be cultivated is of such an inferior degree of fertility that it yields barely enough to enable its cultivators to survive and rear the number of children required to replace them. At that point, all output on better grades of land that is in excess of what is required for such minimum subsistence shows up as "land rent."

If, for example, we assume that 80 units of product represents subsistence, then, as we have just seen, a rent of 10 would be reached on land of the second quality, and 20 on land of the first quality. This would represent a kind of equilibrium. Rent could not grow further, because population could not grow further—an additional population could not be sustained, because yields would be too low to support it. (Eighty units of agricultural output, remember is assumed to represent minimum subsistence. Land of the fourth quality yields less than subsistence, say, 70 units.)

To develop further the case thought to exist against private ownership of land, we must consider what allegedly would happen if some improvements in production were now made—improvements that would increase the output of labor and capital on all the different grades of land. For example, suppose that with the use of the same

labor and capital, first-quality land could now yield 110 units of product; second-quality land, 100 units of product; and third-quality land, 90 units of product. For a time, everyone would be better off. But then, precisely as a result of the greater prosperity, more children would survive to adulthood, population would grow, more land would need to be cultivated, and it would become necessary to resort to land of the fourth quality, which now yielded 80 units of product and could therefore support its cultivators.

The great mass of people, who lived by their labor, would end up no better off than they had been before. From their point of view, the long-run effect of the improvements would simply be that a larger number of them survived at the edge of subsistence. Land of the fourth quality, which before could not be cultivated, because it yielded less than subsistence, would now yield subsistence and would be cultivated. Rent would commence on land of the third quality, which previously yielded no rent, and would increase on all the higher grades of land. Thus, the increase in yields on all the different grades of land previously cultivated would end up in the pockets of the landowners as additional rent, while the great mass of people toiled on at subsistence.

It was on the basis of this analysis that Ricardo and many other classical economists concluded both that the “natural” or equilibrium level of wages is subsistence and that rent tends to constitute a larger and larger proportion of the total income of a country as the country grows in wealth and population.⁵¹ (The alleged tendency of wages toward subsistence was widely believed to be so inescapable that the proposition gained the name “*the iron law of wages*.”) In fairness, it must be pointed out that Ricardo sometimes admitted that in an improving country wages might stay ahead of their so-called natural level for an indefinite period of time.⁵² But he could not free himself from thinking of subsistence as representing the natural equilibrium.

Ricardo’s views are understandable if one keeps in mind when he lived, and that his knowledge of history referred to the centuries prior to the Industrial Revolution. The five hundred years from 1250 to 1750 strongly appeared to confirm his view that economic improvements benefit primarily the landowners, while leaving the position of the masses unchanged. Those five hundred years represented a period of significant improvement when considered from beginning to end. Yet the standard of living of most people was hardly touched. The major beneficiaries by far were the landowning aristocracy and those merchants and artisans who enjoyed their patronage. By the end of the period, the landowning aristocrats could afford magnificent homes, fine furniture, fancy clothing, and gilded coaches. But the mass of people still

could not afford new clothing, meat, or, often, even enough bread to still their hunger.

While Ricardo himself did not advocate the nationalization of land or the confiscatory taxation of land rent, others did.⁵³ His theory led people to view landowners as receiving the greatest incomes in the society and doing the least to earn them—as passively sitting back and pocketing the fruits of progress and other people’s labor, by virtue merely of the growth of population. It should not be surprising that demands were soon made that these apparently unearned gains be used for the good of all.

These views on land and land rent exert an important, if not generally recognized, influence on public opinion in the present-day United States. They provide much of the intellectual basis for proposals that have been made to nationalize the American oil industry, and for the so-called windfall profits tax that was enacted when price controls on domestic crude oil were removed. For essentially the same analysis respecting the formation of rent applies to mining, and the extractive industries generally, as applies to agriculture. Thus, the rise in the world price of crude oil is widely seen as the result of a growth both in world population and in average oil usage per capita pressing upon limited reserves of oil. The owners of the reserves are perceived as undeserving beneficiaries of this process. The objective of the nationalization proposals and of the windfall profits tax is to seize these allegedly undeserved gains and use them for the alleged general welfare.

These views on land and land rent play a major role in perpetuating the U.S. government’s enormous landholdings in the Western states and in Alaska. In many of the Western states, the federal government owns over half the land; in Alaska, it owns about 99 percent. It is thought that in government hands the land serves everyone, while in private hands it would merely provide unearned income to its owners. These views also influence public opinion in its appraisal of conditions in other countries. It is taken for granted that a precondition of overcoming poverty in many of the backward countries is “land reform,” by which is meant the confiscation and redistribution of all significant-sized landholdings. The economic intent of these proposals is to give to small cultivators the allegedly unearned rents now going to the large landowners.

In this last connection, it must be pointed out that the Communists and socialists are more consistent than the advocates of land reform. Land reform would transfer land rents to a larger number of people than had received them before, but would leave the basic conditions complained of unaltered: those cultivators to whom the better grades of land were given would earn more for the same labor than those to whom the poorer grades were given.

And those working the poorest grades of land would receive no benefit at all. Nor would the dwellers of towns and cities receive any benefit. The Communists and socialists, on the other hand, advocate the nationalization of the land, rather than its redistribution, and thus the use of the land rents for the alleged benefit of the whole society.

How Private Ownership of Land Reduces Land Rent

The inference, so easily drawn from Ricardo's theory, that private ownership of land enables landowners passively to sit back and pocket the fruits of economic progress and other people's labor, is utterly mistaken. The truth is exactly the opposite: namely, private ownership of land is an essential foundation of economic progress, and the more it is respected, the more rapid is economic progress. Thus, it is precisely private ownership of land that prevents land rent from constituting an ever growing share of income. For private ownership of land operates to increase the productivity of land and thus reduce its scarcity value and rent.

We can begin to understand the effect of private ownership of land on land rent if we look again at the case of economic progress and a rise in yields on all grades of land. Only this time, let us consider a far more rapid rate of progress than before, the kind of rate of progress that results from the incentives and ability to increase production that is made possible by unrestricted private ownership of land and which is therefore rapid enough to outstrip the growth in population. For the sake of simplicity, let us assume that the rate of increase in output per worker in agriculture is twice the rate of increase in population. Thus, by the time that population doubles, the same absolute number of workers employed in agriculture is capable of producing quadruple the agricultural output.

In this case, there can be a doubled *per capita* consumption of agricultural commodities without the employment of any additional workers in agriculture whatever. If, as is entirely possible, a doubled per capita consumption of agricultural products is all that the public is prepared to pay prices for that are profitable to the producers, then the effect would in fact be that the number of workers employed in agriculture is no larger than before. Because the doubling of population would mean a doubling of the total number of workers in the economic system, the implication of agriculture continuing to employ only the same number of workers would be that the size of agriculture relative to the rest of the economic system is cut neatly in half. And with this halving of the relative size of agriculture would be a halving of the size of agricultural land rents relative to the total income of the economic system.

In terms of physical agricultural produce, agricultural land rents would quadruple: Where before there were three workers respectively producing 100, 90, and 80 on land of the first three qualities, there would now be three workers respectively producing 400, 360, and 320. Therefore, in terms of physical produce, land rents would now be 80 plus 40, instead of 20 plus 10, or four times as large.⁵⁴ That is, they would maintain the same proportional relationship to the four-times larger agricultural produce. What is different, however, and this is vital, is that agriculture itself would now be only half of its former size relative to the rest of the economic system, and thus those land rents as a percentage of the incomes earned in the economic system would be cut in half. And their relative significance would be halved again and again, every time the same set of developments was repeated.

Of course, it is not necessary that when the productivity of labor in agriculture doubles relative to the increase in population, the per capita consumption of agricultural commodities also doubles. It might increase by less than double or by more than double. If it increased by less than double, then a smaller absolute number of workers would be needed in agriculture than before, and thus the relative decline in agriculture and in the economic significance of land rent would be all the greater. Indeed, in this case, there would also be a need for less land under cultivation than before (and for the less intensive cultivation of the land that remained in production). For example, it might be that instead of the doubled population wanting to buy, at prices profitable to the sellers, the 1080 units of agricultural output now produced on the first three grades of land (400 + 360 + 320), they only wished to buy the 760 units now produced merely on the first two grades of land. This would still represent a significant increase in the per capita consumption of agricultural commodities, namely, a little over 40 percent. For 760, the output now produced on the first two grades of land is more than 2.8 times as large as the output previously produced on the first three grades of land (100 + 90 + 80, which equalled only 270), and thus, when divided by a doubled population, represents per capita consumption at a level 1.4 times as great. Yet it would also mean the withdrawal of land of the third quality from production. And this, in turn, would mean a further decline in land rents, this time even as a proportion of the physical volume of agricultural produce. In terms of the physical produce, land rent would now be $\frac{40}{760}$ instead of $\frac{30}{270}$, that is, about 5 percent instead of about 11 percent.

It makes no fundamental difference if the increase in the per capita consumption of agricultural commodities is so great that to provide it, it is necessary to increase the absolute number of workers directly or indirectly

contributing to the production of agricultural commodities, so long as there continues to be a substantial enough decline in the *relative* number of workers so employed. In this case, even though more labor is directly or indirectly applied to each unit of land, and even though the amount of land under cultivation may be increased through the resort to land of relatively inferior quality, still the relative decline in the size of agriculture outweighs any increase in the proportion of agricultural produce which constitutes rent. Moreover, it should be realized that even when it is necessary to resort to additional land, it is possible for land rent as a proportion of the physical volume of the produce not to increase, or, indeed, even to decrease. This will be the case insofar as it becomes possible to make previously submarginal land the equivalent of land of above-marginal quality. To the extent that this occurs, the need to resort to additional land does not mean a need to resort to land of relatively inferior quality.

Under the kind of economic progress I have just described, which has been characteristic of the Western world since the Industrial Revolution, there is no tendency either toward a fall in real wage rates to subsistence or toward a rise in the economic significance of land rent—that is, no tendency toward a rise in the share of so-called national income constituted by land rent. On the contrary, under these conditions, real wages go on rising further and further above subsistence and the share of national income constituted by land rent is radically reduced.⁵⁵ And this is true despite rapid increases in population. Indeed, as will be shown later in this chapter, in the context of a division-of-labor, capitalist society, the very increase in population itself tends to become a major source of the productivity of labor outstripping the increase in population.⁵⁶

Historically, the rate of economic progress in Britain and North America began to accelerate markedly starting around 1750, and by the early nineteenth century was far outstripping increases in population and the consequent operation of the law of diminishing returns and the need to resort to inferior grades of land. In the course of the nineteenth century similar developments occurred in various countries on the European continent.

A succession of radical improvements, continuing right down to the present time, has enormously increased the productivity of labor and the yields per acre on all grades of agricultural land. As I pointed out previously, the poorest land cultivated in the Western world today is vastly more productive than the very best land in use a couple of generations ago, let alone in Ricardo's day. Modern technology, it is worth repeating, is able to make mountains and deserts into land that is far more productive than the very best lands cultivated not many decades ago.⁵⁷

This same process, of converting previously submarginal land into very high-quality land, was exemplified in a different form by the improvements in ocean and overland transportation that took place throughout the nineteenth century. Before the days of low-cost ocean transport, practically all of the land of North America had to be considered submarginal from the point of view of Britain and Western Europe. Before the days of the railroad, most of the land of the American Midwest had to be considered submarginal from the point of view of the Eastern United States as well as the rest of the world. But with these improvements, the land of the American Midwest emerged as an enormous addition to the supply of very-best-quality land. In the Eastern United States, in places like New York, Vermont, and Massachusetts, there are actually substantial tracts of land that at one time were farmed, but have since been put back to forest, because they were displaced by the competition of far superior Midwestern lands. Similar developments occurred in Great Britain in the nineteenth century, where substantial acreages that had been farmed were turned to pasture.

The resulting sharp decline in the economic significance of land rent can be seen by comparing the locus of wealth in Great Britain in 1850 with its locus in 1750. In 1750, the locus of wealth in Britain was great landed estates. In 1850, it was far and away industry and commerce. This change in the locus of wealth was the result of the continual shrinkage in the relative size of agriculture and the corollary continual enlargement of the rest of the economic system, then principally consisting of manufacturing and commerce.

The same course of development that has been described with respect to agriculture took place, of course, with respect to mining as well. Since the Industrial Revolution, the poorest-quality mines in commercial operation at any given time have tended to be far more productive than the very best-quality mines in operation a generation or two before. And the proportion of the labor force employed in mining, and the relative economic significance of mining and mining rents, has sharply declined.

This rapid rate of increase in agricultural and mining productivity has not been a mysterious accident. It is the result, as I have said, precisely of the private ownership of land and natural resources. The private ownership of land and natural resources gives each individual owner the incentive to improve his property, to use it for the benefit of the market, and to go on seeking ways to increase its efficiency and yield. Competition among the various private owners leads to the rapid widespread adoption of whatever improvements are introduced and requires that anyone wishing to go on earning a high rate

of profit introduce still further improvements.

In other words, the combination of the incentive to save and accumulate capital, the profit motive, and the freedoms of individual initiative and competition that private ownership establishes, operates to increase the yield of agricultural and mining property rapidly and steadily, and thus to *reduce* land rent! Private ownership increases the productivity of land, which counteracts diminishing returns and the need to resort to inferior grades of land. In this way, *private ownership of land reduces land rent*.

To present the same idea in still different words, a growing significance of land rent is the reflection of an increasing scarcity of the better grades of land. Private ownership of land, on the other hand, provides the incentives and the means for making each piece of land more productive and for bringing into production every piece that is better than what is presently in use. It is thus the most powerful force operating in favor of abundance and against any growing scarcity of the better grades of land. Thus, it works to reduce land rent and its economic significance.

This principle—that private property is what reduces the significance of land rent—is confirmed if we examine the historical facts. The beginning of the more-rapid rate of progress in agriculture and mining coincides with a *vast extension of the institution of private property in land*. In the century and a quarter or so following 1750, practically the whole of the territory of the United States east of the Mississippi River and extending several hundred miles to the west of it became private property. In addition, the second half of the eighteenth century was the major period of the *enclosure movement* in Great Britain. This was a movement that established private property in land where before there had been communal property. The enclosure movement converted village-owned pastures and forests into separate private property holdings; it also consolidated into larger, compact units the small, scattered strips of land that many villagers had previously farmed. The result was the large-scale creation of modern private farms in Britain. This was followed by the rise of scientific farming: selective animal breeding, the development of newer and better strains of seed, and the application of more modern tools and implements.

Furthermore, both in Britain and on the continent of Europe, the power of feudal laws and customs was broken in other respects as well. Property which had previously been prohibited from being sold, or even leased on a long-term basis, because it was viewed as having to provide support for an unbroken line of future aristocratic descendants rather than being the private possession of any living individual aristocrat, was now

allowed to be sold or leased on long term. This made possible the transfer of such property to more efficient hands. Also, the corollary of the abolition of serfdom on the European continent—which did not take place in most countries until after the French Revolution—was that landowners could now fire unnecessary workers. (Serfdom had not only prohibited workers from leaving the feudal estates of their birth but also prohibited the feudal “owners” from removing them.⁵⁸) Thus, the abolition of serfdom gave landowners a powerful incentive to seek more efficient methods of production, which incentive had previously been lacking because of feudalism’s violation of the right to fire along with the right to quit.

In all these ways, it was the extension of private ownership over a vastly greater area that brought about continual doublings and redoublings of the productivity of labor in agriculture and mining. Thus it was private property in land and natural resources that made it possible for a steadily declining fraction of the labor force to supply a growing population ever more abundantly with agricultural commodities and minerals, and which thus reduced the scarcity of productive land and thereby the economic significance of the income derived from such land.

In our own day, the principle that private property reduces land rent is dramatically confirmed by the oil situation. As explained previously, the U.S. government’s ownership of vast land areas in the Western states and in Alaska operates to keep vast amounts of oil off the market. The same is true of its ownership of the continental shelf. If these areas were privately owned, or open to the establishment of private ownership, the most profitable use to which they could be put would be to develop them and extract and sell the oil they contained. The effect would be vastly more oil on the market and thus a lower price of oil. The effect of this, in turn, would be a reduction in the so-called mining rents derived from owning oil deposits and a reduced significance attaching to the ownership of oil deposits. This result would be achieved the more strongly, the more the territory throughout the world that was privately owned. For then the greater would be the volume of oil deposits under the control of people who had an incentive to develop them and extract and sell the oil they contained.

The result would also be achieved the more strongly, the more the property rights of the existing private owners of oil deposits, and of all other forms of energy deposits, were respected. If, for example, the owners of existing privately owned oil deposits are not forced to operate under price controls, rising taxes, or the threat of confiscation through nationalization or antitrust “divestitures,” they will invest more and produce more oil. By

the same token, if the property rights of the owners of natural gas deposits, coal mines, and uranium mines are not infringed, they will produce more of these forms of energy, which, of course, compete with oil and whose more abundant production would keep down the price of oil and any mining rents derived from the ownership of oil deposits.

Thus, private property and respect for the rights of its owners is what holds down and actually reduces the significance of land rent. However paradoxical it may seem, the objections and criticisms that Ricardo's followers raised against private ownership of land should have been directed against the *absence* of private ownership of land and against violations of the rights of existing private owners. For it is the absence of private property, and the violation of property rights in land, that hold down the supply of agricultural and mineral products and thus bring about a scarcity of the better grades of land and mineral deposits and so increase the significance of land rent. It is precisely government intervention at home and the worldwide nationalization of oil deposits that have made possible the emergence of a new aristocratic class of officials and sheiks, who derive enormous revenues through absolutely no productive contribution on their part. Abolish that intervention and open more land to private ownership, and the rents derived from the ownership of oil deposits will be radically reduced.

It is worth pointing out in connection with the fact that private property is the basis for the reduction of land rent, that efforts to tax away the land rents that do exist under private property only serve to increase land rents. For in reducing the income that can be derived from the ownership of a piece of land, they reduce the incentive of landowners, and the means available to landowners, to improve their methods of production and thus to bring about reductions in land rent. Thus, such taxation deprives the average wage earner of an essential defense against the consequences of rising population, which, in the absence of rapid and continuing progress in agriculture and mining, would be the unleashing of the law of diminishing returns against him, and all that that implies.

In addition, of course, it should always be kept in mind, on the basis of the discussion of natural resources in Chapter 3, that the increase in the supply of agricultural and mineral products that private ownership of land achieves is not at the expense of the future. On the contrary, the increase is progressive and can go on virtually without limit, so long as man expands his knowledge of and power over the physical world in which he lives, which is precisely what private ownership of land and natural resources gives him the incentive to do.⁵⁹

Land Rent and Environmentalism

Knowledge of the role of private ownership of land and natural resources in preventing any tendency toward a progressive growth in land rents and decline in real wages toward an equilibrium of subsistence confirms the critique of environmentalism made in Chapter 3. We have already seen the role played by environmentalism in the rise in mining rents in connection with petroleum, and the consequent enrichment of Arab sheiks and terrorist governments at the expense of the rest of the population of the world.⁶⁰ It is necessary to realize that in general, as a matter of principle, the environmental movement is bent on stopping further increase in, indeed, on reducing, the productivity of labor in agriculture and mining, and thereby, whether it is aware of the fact or not, on driving down real wage rates and raising land rents. This is the meaning of its systematic efforts to stop the use of pesticides, herbicides, and chemical fertilizers, and of its further systematic efforts to stop the conversion of previously submarginal land and mineral deposits into highly productive land and mineral deposits—notably its efforts to stop the economic exploitation of “rainforests,” “wetlands,” the Arctic, Antarctica, and the ocean floors, as well as much of the American West and Alaska. The measure of its success must be the rise in the economic significance of land and mining rents and a decline in the level of real wages toward subsistence.

The environmental movement openly declares its hostility to the Industrial Revolution, which masses of unthinking people take to mean opposition merely to black smoke belching from factory chimneys. It should be clear from this analysis that the fact is that even if environmentalism does not succeed in removing modern technology from the world, it can easily succeed in recreating pre-1750 conditions for the masses of people in the presently advanced countries, merely through throttling further rapid progress in agriculture and mining. The environmental movement is often characterized as elitist. It is elitist. Economically, it is a latter-day movement of feudal aristocrats, seeking the existence of a privileged class able to pocket the benefits of the economic progress that has taken place up to now, while denying those benefits to the broad mass of the public. It is a movement of monopolists, typified by the mentality of homeowners of the type who, having gotten “theirs,” seek to stop all further development of land in their area. It is the movement of neofeudal mentalities who desire a world of broad open spaces for themselves, spaces that are essentially ownerless, and who care nothing for the plight of crowded, starving masses, who are to be denied the benefit of access to those open spaces, which are to be closed to all development. Essentially it is the old story of the feudal lords who are to have vast forests set

aside for their enjoyment, while the serfs dare not remove a log for their fires or kill an animal for their meal.⁶¹

The Violent Appropriation Doctrine

It is necessary to consider the argument that the institution of private property in land is tainted insofar as present titles can be traced back to the violent dispossession of previous owners.

As noted in Chapter 1, this argument has its clearest application to conditions in Europe, in the course of whose long and bloody history probably many violent transfers of ownership can be found in connection with almost any particular piece of land.⁶² It is doubtful that even on its own terms the argument has much application to the United States. To be sure, in the process of appropriating land, occasional injustices were committed against Indians. These injustices, however, arose only in those isolated cases in which individual Indians could claim legitimate rights of private ownership which the white settlers violated, such as having established a farm which white settlers appropriated. There was no injustice present in the settlers disregarding the claims of the Indian tribes to political sovereignty over territory, nor in their disregarding the collectivist claims of the tribes to economic ownership. By the principles set forth in the Declaration of Independence, governments are instituted among men to secure their inalienable individual rights and deserve to be overthrown when they become destructive of that end. If this was true of the relatively enlightened despotism of the British under George III, it was infinitely truer of the barbaric governments of the Indian tribes and their arbitrary claims to land ownership.

In the United States, the settlers found an almost empty continent, whose relative handful of inhabitants almost all lived by hunting and who had few or no fixed settlements, nor, therefore, any solid basis for claiming title to the land, over which they merely roamed. And, even so, the settlers frequently paid the Indian tribes for the relinquishment of their claims to rights of hunting and camping. In this sense, they purchased Manhattan Island and many other, far more substantial pieces of territory from the Indian tribes. Thus, in the United States, it is true to say that the historical record of the overwhelming majority of property holdings is free of violent appropriation—that practically all property holdings can be traced back through voluntary purchases and sales to a point of peaceable appropriation from nature on the part of their very first owners.

Moreover, it should be realized that in any case in which a division-of-labor, capitalist society supersedes a non-division-of-labor society, it is logically illegitimate to view matters in the light of forcible expropriation. The conditions of a non-division-of-labor society are neces-

sarily those of recurring conflict and warfare, with successive waves of newcomers again and again forcibly displacing the previous inhabitants. This is the necessary outcome of population growth and the operation of the law of diminishing returns within the narrow constraints of a society of hunters, nomads, or self-sufficient farmers. In such circumstances, as soon as population growth reaches the limit of the ability of a group's present territory to support it, its members must range further afield, in the quest for additional hunting grounds, pastures, or agricultural land. And thus they come into conflict with the members of other groups who seek the same territory or who already occupy it, and whose survival likewise depends on its possession. It is only the establishment of a division-of-labor, capitalist society, with its potential for continuing increases in production, that removes these economic causes of conflict and makes possible a harmony of interests among men. It is only within such a society that property rights or any other rights can be secure.

It should also be realized that in any conflict between a division-of-labor, capitalist society and a non-division-of-labor society, such as existed between the society of the American settlers and those of the Indian tribes, the former possesses an overwhelming and decisive *moral* superiority over the latter, which absolutely entitles it to victory. This superiority is the fact that the division-of-labor society possesses the ability to *assimilate* all of the members of the non-division-of-labor society, and to enable them and their heirs to enjoy greater wealth and longer life, along with those who are already members of the division-of-labor society. But the non-division-of-labor society cannot assimilate the members of the division-of-labor society—it cannot even support all of its own members. Thus, while the division-of-labor society of the American settlers had the ability to offer the Indians the life of the settlers upon assimilation, the non-division-of-labor society of the Indians offered only the prospect of starvation and death if the settlers were to attempt to assimilate with it. The conflict between the settlers and the Indians was a conflict between a society easily capable of absorbing an additional million members, and a society capable of sustaining no more than a million members (despite the availability of most of the land mass of the North American continent), for that was the population limit that the Indians were apparently unable to go beyond, before encountering a shortage of hunting grounds. If any failing can be charged to the settlers, it was their failure sufficiently to seek to assimilate the Indians. But this was probably the result of the refusal of the Indians to be assimilated.⁶³

Furthermore, it must be stressed that in any case—even aside from that of conflict between a division-of-

labor society and a non-division-of-labor society—the legitimacy of the institution of private property and of the title of its present owners does not in any way depend on the absence of violent appropriations in the past. Private property in Britain and France, for example, and the title of its present owners, is fully as legitimate as it is in the United States, despite a record of violent appropriations in the past. The reason for this is that in a division-of-labor society, such as Britain and France represent, there is a powerful force at work which steadily operates to wash away all stains of past violence. This is the fact that in such a society production is carried on for the market and that property is gained or lost to the degree that one produces to the satisfaction of the market.⁶⁴

To illustrate this principle, let us assume the existence of a society in which every piece of property has been violently seized from its previous owners. But let us also assume that from this point forward there is an end to violent appropriation, because the law now recognizes the last group of violent appropriators as the legitimate owners. Henceforth, acts of violent appropriation occur in violation of the law and are prosecuted and severely punished, and thus, from this time forward, property which is not passed by inheritance must be acquired by no other means than by voluntary purchase and sale.

Thus, from this point on, the owners of property are secure in their possession and have the incentive to improve their property and its ability to produce. In the context of a division-of-labor society which grows up around them, the incentive to increase production means the incentive to produce more for the market, in order to be able to earn the money to buy the things one wants in the market. An essential means of increasing production for the market is the increasing use of capital in the form of money, so that one's production can have the benefit of products previously produced by others and the benefit of services voluntarily performed by others. Capital must be used in order to purchase such things as animals, tools, building materials, equipment, and labor services, which are essential to being able to increase production for the market. There is no alternative to making such purchases if one wishes to be able to earn the money one would like to earn.

In the very process of raising capital, however, it becomes necessary either to sell land or to borrow against it. Such sales of land are obviously an important way in which land passes into the hands of people who have no necessary connection with violent appropriators.

Furthermore, the necessity of using capital—of making purchases in order to make sales—creates the possibility of financial losses. Such losses are certain to occur for many landowners as the widespread efforts of land-

owners to increase production for the market result in lower prices. Only the more efficient landowners—those with lower costs—can be profitable in the face of such lower prices. The less efficient ones suffer losses.

Thus, the newly established security of property and its incentives to save and invest and increase production result in market competition among the landowners. In this competition, some of the landowners succeed and grow richer, while others fail and lose their land. They lose their land either because they have borrowed against it, and their losses prevent them from meeting the interest and principal payments, or simply because to offset financial losses and continue producing with the aid of capital—of the means of production that can only be obtained with the expenditure of capital—it becomes necessary to sell more land. Ultimately, of course, a landowner who continues to sell at losses must lose all of his land.

Thus land more and more passes into the hands of those who acquire it on the basis of their success in serving the market, and is retained only by those who are successful in serving the market.

Moreover, the purchase of land, of course, is not limited to those who have been previous owners of land. It is open to everyone, including (very importantly in the context of the transition from feudalism to capitalism) former serfs and the descendants of serfs. Under these conditions, anyone, irrespective of his class of origin, or that of his ancestors, will be in a position to acquire land who earns the money necessary to buy it or who offers good prospect of efficiently using the land he acquires. (This second condition is a principal basis for being able to borrow money to buy land.) The money with which to buy land can, of course, be earned in any area of the economy, whether the accumulation of profits in manufacturing or commerce or the saving up of wages in any line of employment, whether in industry or in agriculture. And, as indicated, money to purchase land can be borrowed on the basis of demonstrated ability and good prospects for its profitable use.

Thus, the basis of acquiring and retaining property becomes the ability to produce efficiently for the market.

Initially, of course, the power to spend in the market of a country that recently experienced a forcible appropriation of property will reflect that forcible appropriation. To the extent that those who have appropriated others' property, or the heirs of these appropriators, are richer, their power to spend is greater, and production for the market is, accordingly, production that serves them. But to the extent that the members of this group are not themselves as adept in producing for the market as those who have not seized property, or whose ancestors have

not seized property, property begins to gravitate away from the members of this group and toward the members of the second group. Soon, a substantial amount of property is held not by those who have seized property, or by their heirs, but by those who have supplied the wants of this group. And now *their* spending emerges as a growing factor in the market. And insofar as property is retained by descendants of forcible appropriators, it is so by virtue of their success in serving the market.

As more time passes, property is increasingly held not by those who seized it, nor by their heirs, but simply by those who are most adept at supplying the wants of others who have money to spend, who, for their part, possessed the same ability. In this way, the significance of the violent seizure of property in the past is steadily diminished and all property comes to be held by those who have fully earned their right to it.

How rapidly this cleansing process takes place depends on how free the market in land is allowed to be. The main obstacle delaying the process is *entail legislation*—i.e., laws that restrict the passage of property to a specific line of descendants, and which prohibit its sale, forfeiture in payment of debts, or even long-term lease, to parties outside this line of descendants. Such legislation (which existed in Europe even after the French Revolution) was enacted to preserve the holdings of aristocratic families in the face of the market forces just described. Of course, entail legislation is itself a gross violation of property rights—it denies the property rights of the living in the name of the alleged property rights of the unborn.

The Demand for Land Reform

The doctrine that present titles are invalid because of past acts of violence in the appropriation of property, is often associated with demands for “land reform.” Land reform is a demand that property be forcibly transferred from its present owners to a new group of owners. The connection to the violent-appropriation doctrine exists whenever this new group is alleged to be descended from earlier possessors whose rights the ancestors of the present owners allegedly violated.

It should be realized that no amount of past violence in the appropriation of land can justify land reform. Land reform is simply a new, fresh act of violent transfer of land. It is one thing for the actual victim of a dispossession, or his children or grandchildren, to demand to be put back in the possession of the property that was forcibly taken from him. But if for any reason these individuals are denied justice, it becomes a fresh injustice to later on dispossess an owner on the grounds that his ancestors, or the ancestors of some previous seller, lacked just title. In order for justice to be done, there must

be a time limit on the recognition of claims for the redress of past injustices.

If this were not the case, no one could be secure in his property. At any time, parties could step forward claiming dispossession of their ancestors by the current owner’s ancestors or by the ancestors of some previous seller of the property. And claims of any one group of alleged victims could in turn be superseded by the claims of still another group of alleged victims able to trace the dispossession of its ancestors further back. In a country like England, for example, the same piece of ground might be contended for by those able to trace the dispossession of their ancestors to the War of the Roses, or, alternatively, to the Norman Conquest, or to the still earlier invasions of the Danes, Saxons, Romans, and even Picts and Celts.

It would certainly be a gross injustice to ask anyone to work and save to improve his property, and then take it from him on the basis of such claims. For justice to be done, conditions must be such that people can work and save to improve their property. And for such conditions to exist, property rights must be put beyond challenge as quickly and as completely as possible. This means, as a minimum, a strict time limit on the recognition of claims based on past injustices.

Once private property rights are made secure, not only are the effects of past injustices washed away, but, as should already be clear, the land of a country is quickly put to its most efficient uses. It is important to stress this point in dealing with the issue of land reform. As the advocates of land reform describe matters, the system of land ownership they seek to overthrow is highly inefficient and has no economic basis. According to them, the actual unit of agricultural production is almost always a small farm, a large share of whose output its peasant operator must turn over as rent to a wealthy landowner who has done nothing to earn it. “Land reform”—the forcible transfer of ownership to the peasant operators—is then urged not only as the means of rectifying past injustices, but also as the means of providing powerful incentives for the improvement of production. As owners, it is argued, the peasant operators will have the incentive to increase their production—something which they now lack, because the increase would allegedly be appropriated by the wealthy landowners.

What must be realized here is that if the “land reformers” were right in their description of the facts, a free market in land would automatically and peaceably operate to transfer ownership to the small operators. For if, as owners, the small operators would have greater incentives and would produce more, and there is no economic basis for the present, large-scale ownership of land, then the present owners would have a powerful incentive to

sell out to the small operators. This is because if the same piece of land presently owned as a single unit would produce more when subdivided into a multiple of smaller property holdings, its total market value would also be greater when subdivided into such holdings. The situation would be perfectly analogous to what happens right now in the United States, as cities expand into surrounding farm or ranch land. The farmers or ranchers who own units of several hundred or several thousand acres find it profitable to subdivide and sell out their holdings in units as small as a quarter or eighth of an acre, or even less, to a larger number of home owners.

If, indeed, small units of ownership were in fact more efficient, the owners of large holdings would have exactly the same kind of incentive to sell out to small owners. And it is worth noting that the small owners would not have to be able to pay for their purchases right away, any more than home buyers need to be able for their purchases right away. The small owners could buy their holdings on credit—with mortgages on their property. This arrangement would probably be advantageous to the present, large owners even if they were the ones who had to hold the mortgages, because for twenty or thirty years they would receive far more as interest and principal payments from land used efficiently than they could otherwise receive as rent from land used inefficiently. This excess of funds received over twenty or thirty years would more than compensate them for the loss of all future rents—in exactly the same way that receipt of a sufficiently high price in the present would more than compensate them for the loss of every subsequent year's receipts.⁶⁵

Thus, even if the advocates of land reform were correct in their claim that the system they want to overthrow is inefficient, all that would be necessary to achieve greater efficiency is not “land reform”—not the forcible expropriation of property—but *the establishment of a free market in land*. If the more efficient system is the breakup of large landholdings into small units, then this is what a free market in land will accomplish—without force or violence, and to the mutual self-interest of all concerned.

But the fact is that the breakup of large landholdings that the land reformers want to achieve by no means typically represents an improvement in efficiency. Often, it is precisely the large landholdings that are the more efficient arrangement and are the product of the market as far as it is free. This appears generally to be the case in instances in which large plantations produce and export such crops as bananas, sugar, pineapples, or coffee. Here the unit of production is not a farm of a few acres but perhaps the whole plantation, or at least some substantial portion of it. The large landholding is necessary

in order to utilize expensive modern equipment, such as tractors, which would be uneconomical if they had to be applied within the limits of separate farms consisting of only a few acres each.

In all cases of this kind, land reform represents a serious reduction in agricultural efficiency—over and above the disincentives its prospect creates for saving and any form of improvements to be undertaken by those likely to be expropriated by it. For it represents a forced reduction in the scale on which agriculture is undertaken, and thus a loss of the benefits of large-scale production.

The advocates of land reform are actually oblivious to all such concerns. Their real goal is not greater efficiency in agriculture, but to enable the largest possible number of people to survive by means of subsistence farming. They want each family to be able to live by having its own few acres. And when there are more families, each will presumably have a little bit less land to farm, as the result of a further land reform if necessary.

If one thinks seriously about land reform as a solution to poverty in the backward countries, it becomes clear that it is actually *incompatible* with the real solution. The real solution to poverty in the backward countries requires not that more people there be able to squeeze by a little bit more easily as farmers, but that the populations of those countries become *integrated into the international division of labor*. If the people of most of Asia, Latin America, and Africa are ever to enjoy a high standard of living, it will not be as farmers on a few acres each, but as workers in the same kind of division-of-labor society as presently exists in the United States, Western Europe, and Japan.

Thus, land reform seeks the solution to poverty in totally the wrong direction. It actually operates to prevent the real solution from being achieved. In forcing the breakup of large plantations producing for the export market, it cuts backward countries off from such connection to the international division of labor as they have managed to achieve. In disrupting the exports of these countries, it deprives them of the ability to import from the more advanced countries, and thus deprives them of the ability to obtain technologically more advanced goods than they can produce for themselves. At the same time, of course, in reducing the production of goods for export and thus raising the prices of the goods affected, it operates to reduce the real wages of workers in the more advanced countries, since the buying power of their wages is correspondingly reduced.

Even more fundamentally, the forcible restriction of the scale on which agriculture is undertaken and the constant threat of renewed confiscations that land reform represents operate to prevent permanently the rise in the productivity of agricultural labor that is indispensable to

building a division-of-labor society. It should be remembered that labor can be spared for industry and commerce only to the degree that it is possible for a fraction of the working population to produce the food required by the whole. Land reform operates to keep down the productivity of the fraction required in agriculture and thus to keep up the size of that fraction. It thus works to prevent the development of industry and commerce and the establishment of a division-of-labor society in the countries in which it exists.

The solution to the agricultural problems of the backward countries is not land reform, but the establishment of a fully free market in land and thus, for the first time in those countries, the full recognition of private property rights in land. That will eliminate all vestiges of feudalism and feudal inefficiency and make possible the progressive improvement of agricultural production.

Our discussion of land reform has application to conditions in El Salvador in recent years. In that country, the government of the United States spearheaded a drive for land reform, even under the auspices of the avowedly conservative Reagan administration. It made land reform a precondition of American aid.

While the official policy of the U.S. government is, and was, supposed to be noninterference in the internal affairs of other countries, this policy was somehow forgotten in the case of land reform in El Salvador. (It has been scrupulously observed, however, in connection with almost all of the nationalizations of industries, including the expropriations of the property of American nationals, that have occurred throughout the world. It has also been observed in connection with Communist atrocities. But the same State Department that helped to lose China and Cuba to communism did not remember the policy of noninterference in connection with land reform in El Salvador.)

It is almost impossible to know the details of what actually happened in El Salvador as a result of land reform, because the representatives of the press lack the knowledge of economics that is required for intelligent reporting on the subject. Nevertheless, reports did come through that the so-called Right in El Salvador, whatever that designation may mean, denounced land reform as a violation of free enterprise and blamed it and the related nationalization of banks for destroying the economy of the country and fomenting the unrest on which the Communists thrived. In view of what has been established in principle concerning land reform, it would seem that such claims deserve thorough investigation. There is a strong likelihood that they are correct.

If they are correct, our government's policy of having made land reform a precondition of American aid would

be ironic in the extreme. It would mean that before we were willing to aid El Salvador in a defense against communism, we required that its government violate private property rights on a massive scale and create the chaos which the Communists needed in order to thrive. (Later, if the Communists had won their revolution, which, until the recent fall of communism in Eastern Europe and the Soviet Union, was the likely outcome, the State Department could have issued a white paper explaining why their victory was inevitable.)

In connection with the subject of land reform, it is necessary to mention the fact that the American military occupation under General MacArthur forced the policy on Japan after World War II. Large landowners were forced to sell at prices set by the government, and rapid inflation of the currency quickly made their compensation almost valueless.

On the basis of all that has been established concerning land reform, it should be clear that this policy must be condemned, even though it is almost universally regarded as having been a major element in establishing American "democracy" in place of Japanese feudalism. The only appropriate policy, the only one consistent with the American principle of individual rights, would have been the establishment of a free market in land—i.e., the abolition of all aspects of entail legislation and any elements of legal privilege for the large landowners, but not their expropriation.

The effect of land reform in Japan has been to hold down the efficiency of Japanese agriculture and to impose a drain on the rest of the Japanese economy, which is obliged to subsidize the inefficient agricultural sector. In Japan today, landholdings are typically no more than two or three acres and are operated on a part time basis, by people whose main employment is in industry.

This highly inefficient arrangement has not resulted in a catastrophe, because at the time it was instituted Japan was already a highly industrialized nation able to import most of its food supplies, and over the years it has greatly increased its ability to import food. The effect of land reform in Japan has thus worked out to be equivalent to that of the destruction of agriculture within the territory of a city, as it were. It has not been disastrous, because the role of agriculture was relatively small to begin with and the losses inflicted on it could easily be made good by a rapidly expanding industrial economy, through imports. Japan's food supply would be affected far more seriously by land reform in the United States, Canada, Australia, Brazil, or Argentina than by land reform in Japan, because these are the places on which it actually depends for most of its food supply. The effect of the Japanese land reform would be virtually nil if not

for the protectionist measures against the import of foreign rice. These force Japanese consumers to bear the burden of the land reform as far as the consumption of rice is concerned.

It must be noted that Japan's postwar industrial success is the result of following policies with respect to industry that are the opposite of land reform. Property rights in industry have been respected far more highly in Japan than in the United States—as manifested in sharply lower rates of taxation on profits and interest. This, of course, has resulted in much higher rates of saving, capital accumulation, and economic progress in Japan than in the United States. Furthermore, since the early postwar years, inflation in Japan has been at a significantly lower rate than in the United States. This is also very important in regard to a country's real rate of taxation of profits and interest, since the greater the rate of inflation, the higher are the artificially inflated profit and interest incomes subject to taxation and thus the greater is the actual taxation of such incomes.⁶⁶

To summarize our discussion of land reform, we have seen how in a division-of-labor, capitalist society the stain of violent appropriations of land in the past is steadily washed away through the operation of market processes. In close connection with this, we have also seen how land reform represents a fresh act of injustice and is economically disruptive and against the interests not only of existing landowners, but also of everyone else in the long run. For land reform seeks to perpetuate agricultural inefficiency and thus to keep down the real income of all buyers of the agricultural products concerned. By the same token, it operates to prevent the development of the division of labor in the countries in which it exists by making impossible the release of labor for industry and commerce. Thus, in the long run, it holds down the real income even of those who are supposed to be benefitted by it. Whatever legitimate objectives the advocates of land reform might have would be achieved by the establishment of a free market in land, not by land reform.

6. Private Property and Territorial Sovereignty

The principles we have established concerning private ownership of the means of production have implications for the extent of the territorial sovereignty of countries.

In history books and discussions of current affairs, one frequently encounters such statements as: The motive of country A in going to war with country B was to obtain the latter's coal mines—or steel industry, or whatever. It

is taken as virtually self-evident in these discussions that the citizens of a country gain to the extent that their country's territory is enlarged to contain more natural resources and more branches of industry.

Our discussion of the general benefits derived from privately owned means of production in a division-of-labor society shows that this belief is false. We have seen that an individual does not need to own property in order to benefit from it, so long as he is able to buy its products. In the same way, *a country does not require sovereignty over a territory for its citizens to be able to obtain all the economic benefits that that territory can offer*. For the most part, they obtain those benefits merely by being able to buy the products of that territory.

For example, in order for the citizens of Germany to obtain the economic benefits of the natural resources and industries of Alsace-Lorraine, it is absolutely unnecessary that Germany own Alsace-Lorraine or that fellow German nationals own those resources and industries. An individual German who wants something from that region obtains it by paying for it. What difference can it make to him whether the producers of the good he buys salute the French or the German flag? Or the Burgundian flag? What difference can it make to him whether they sing the "Marseillaise" or "Deutschland Über Alles"? How are the goods, or their price, affected by such matters?

The only rational political-economic interest that the citizens of a country have in the territory of other countries is that that territory be *under a free government*. (And that, of course, is their first and foremost real interest with regard to the territory of their own country as well.) If a country is under a free government—i.e., a government that is limited to defending the individuals in its territory from the initiation of physical force—then its territory offers to the entire world every economic benefit that can possibly be derived from it. Not only can all the world buy its products, but all the world is free to try to improve the development of its natural resources and industries. For in such a country, foreigners have the same right as nationals to own land, invest capital, and to live and work. Thus the products available for purchase from such a country are as good and as inexpensive as it is possible for them to be in the circumstances. Anyone anywhere in the world who sees a way to make them still better or cheaper is free to go ahead and try to do so.

There is absolutely no rational economic basis for any country to seek sovereignty over the territory of any other country that has a free government. For its citizens already derive all the economic benefits they could derive if it were under the sovereignty of their own government. Indeed, if their own government is less free than

that of the foreign country under consideration, they would almost certainly derive *less* benefit from the foreign country's territory if it were brought under the sovereignty of their own government. As an extreme example, the citizens of Soviet Russia would have died of starvation if the territory of the United States had come under the sovereignty of the former Soviet Union and shared its economic chaos.

The major implication of this discussion is that in a world made up of free countries, there would be absolutely no rational economic basis for war or imperialism. It would make no difference to anyone what the extent of the territory controlled by his own government was. He would be perfectly free to buy and sell anywhere, to invest anywhere, and to live and work anywhere, irrespective of whose flag flew over the territory. Thus, there could be no rational economic motive for the citizens of any country to seek an extension of their own country's sovereignty, and thus no economic grounds for war.⁶⁷

A rational economic motive for interfering with the sovereignty of other countries arises only insofar as they lack free governments. And then, the only rational economic purpose of such interference is to establish a free government. For example, if there is an area rich in low-cost natural resources, but anyone who tries to develop them has his property confiscated and runs the risk of being murdered, then the rest of the world is deprived of the benefit of those resources. Its interests would be served by the establishment of a free government in that area.

It must be acknowledged that the British Empire in the nineteenth century by and large served as just such an instrument. It was the means of establishing relatively free governments in many areas of the world that would otherwise have remained in a state of anarchy or despotism. Its existence served to open vast territories to economic development that benefitted the entire world. It was not only the citizens of Great Britain who gained by the entry of those territories into the world market, but people everywhere. Every buyer of rubber and tin everywhere in the world benefitted from the fact that British rule made possible the development of the Malayan rubber plantations and tin mines and thus a more abundant and less expensive supply of rubber and tin. Every buyer of cotton, flax, linen, jute, and all the other products of India benefitted from the fact that British rule made possible the development of the production of these things in India. This is not to excuse the racist attitudes that were often displayed by the British in their colonies, nor any of the injustices they committed in the course of colonial rule, but it is to acknowledge the genuinely great accomplishment that their empire represented.

A Defense of Foreign "Exploitation" of Natural Resources

It is necessary to point out that foreign development and export of a country's natural resources in no way represents a loss to the native population of that country. It is not economic "exploitation" in any evil or improper sense. For example, the fact that the British developed the tin mines of Malaya and then exported the tin throughout the world was no more a loss to the Malayan population than it is a loss to the people of Minnesota that the iron mines of their state were developed by businessmen from New York and Chicago, who in turn have exported the iron throughout the rest of the United States and the world as a whole.

The belief that such activity represents "exploitation" is based on the premise that natural resources are rightfully the collective property of the population of the territory in which they are found. Those who hold this view then observe that only the private owners are paid for the extraction of the resources sent abroad, and that much of the money received for the resources remains abroad. On this basis they conclude that a territory's property is being taken from it without compensation.

The answer to this view is that land and natural resources do not properly belong to the people of a territory collectively, but to specific private individuals and companies. For all the reasons I have shown, private ownership is the key to the development of natural resources and thus to the general population of the world being able to benefit from their existence. Collective ownership means nondevelopment or, at best, inefficient development and therefore less general benefit from the existence of natural resources.

The inefficiencies of collective ownership operate to prevent much or any gain from being realized by the countries that enact collectivization—at least where the collectivized resource deposits must compete with privately owned deposits whose operators are not prevented from expanding their activities. Furthermore, whatever the citizens of a given area might gain by the collective ownership of a natural resource in their territory is always at the expense of the greater loss of others. There is not only the loss of the private owners, whose property is collectivized; there is also the loss of the buyers of the resource and its products, for whom the resource is made less abundant and more expensive. In addition, there is the loss of sellers of other products and resources whose sales revenues and incomes are diminished because buyers have less funds available to buy their products because of the necessity of paying more for the higher-priced collectivized resources. (For example, the gains of the members of OPEC were at the expense of the greater loss of the buyers of oil and of the sellers of other products

for which the demand was diminished because of the high price of oil.) The net effect of collective ownership and its inefficiencies is that while some sellers may take in more money, other sellers take in equivalently less money, and at the same time the same total expenditure of money, which constitutes the revenues of all sellers combined, buys less. Thus reduction in production is the net loss to the world.

And, finally, to the degree that collective ownership is carried further, any gains associated with it from the point of view of the citizens of any particular territory are lost back in the form of less abundant supplies and higher prices for everything that depends on natural resources found in all other territories where collective ownership exists. Thus, whatever the citizens of Malaya or Minnesota might gain by collectivizing the tin or iron mines of their country or state would not only be more than offset by the losses of others, but it would also be offset by less abundant supplies and higher prices of all the things consumed by Malaysians or Minnesotans insofar as those things were also produced under conditions of collective ownership of the natural resources involved. The consequence of collective ownership of natural resources applied as a general principle is that everything would be more expensive to everyone. And many of the collectivized resource deposits would not even be able to operate at all for a lack of other resources or of products made from those resources. For example, some of the collectivized tin mines could be made inoperable by the inefficiencies of collectivized iron mines, which resulted in the cost of tin-mining equipment being made too high. The inefficiencies of collectivized iron and tin mining together would operate to reduce the availability of equipment for extracting oil and coal; the inefficiencies in the production of these latter would also work against the production of iron and tin, and so on.

It should be realized that in fact the foreign development and export of natural resources is a source of gain not only to the general population of the world, through bringing about a more abundant and less expensive supply of the resource, but also to the *general population of the specific territory in which the resource is found*. For it means foreign investment in the area and thus a greater demand for local labor and therefore higher local wage rates. It also means the ability of the local population to obtain imports from other countries, because to the extent that it produces products that are exported, its wages are paid with funds earned abroad. The imports obtainable with these funds include not only products made from natural resources found throughout the rest of the world, but also products of modern technology that it would otherwise be impossible to obtain in the area.

If the local population would like to see foreign in-

vestors spend locally a greater proportion of the revenues they earn abroad by exporting natural resources from the area, then the basic thing they must do is respect the rights of foreign investors. Foreign investors will spend more locally—in the form of increasing their investments—if they judge that investment in the area is profitable, which, in the long run, presupposes that it is secure from depredations by the local government and the local population.

It should also be realized that the profitability of foreign investment depends on the ability of the investors to withdraw their funds whenever they wish. It is one thing for an investor living in London or New York to be willing to invest his money in Malaya or Minnesota. It is a different thing to require, in effect, that he live there in order to be able to enjoy the profits from his investment. Yet that is the effect of laws that interfere with the remission of dividends and interest abroad. Outsiders will readily invest in an area that offers the prospect of high profits if they know that they are free to enjoy their profits elsewhere and free to withdraw their funds to take advantage of the possibility of still more profitable investment opportunities elsewhere.

To the extent that they possess free governments, backward countries naturally offer a very powerful attraction for outside investors—namely, their low wage rates. To the extent that foreign investment can raise the productivity of labor in the backward countries toward the level at which it exists in the more advanced countries, those low wages represent lower costs of production and thus higher profits in comparison with investment in the more advanced countries. If foreign investors judge that their investments are secure in such a country, it is able to attract a veritable flood of investments. And the high profits earned on those investments are plowed back to create still more local investment. On just this basis, we can observe spectacular rates of economic progress today in such countries as Taiwan, South Korea, and Singapore. The rapid progress of Japan, too, was explainable until not too many years ago on the basis of the constant reinvestment of high profits earned on the basis of relatively low wages.

The effect of all this additional investment, of course, is to *raise* local wage rates more and more, and to bring the economy and general standard of living of the area to a higher and higher level, until what began as a backward country is transformed into a fully modern country with a very high standard of living. This has already happened in Japan, where wages are now among the highest in the world and are comparable to those in the United States. The same process is well underway in the other countries named.

Moreover, it should be realized that as local wages rise, the ability of the local population to save and invest on its own increases, and thus that more and more businessmen can come from the ranks of the local population. In other words, the conduct of local business automatically comes to include a growing proportion of natives. And some of the native businessmen, of course, can themselves choose to operate internationally. In this and all other respects, the local area comes to be fully integrated into the world economy. Again, Japan, South Korea, and Taiwan are outstanding examples of this process.

Thus, if they possessed free governments, many of the backward countries of the world could be very rapidly developed into fully modern countries. What prevents this is their belief that foreign investors are their enemies and should be expropriated. This stops foreign investment and perpetuates the backwardness of these countries.

To avoid possible misunderstanding, there is no intent to imply here that the problems of the backward countries are purely political. More fundamentally, they are philosophical and cultural. In many cases the influence of irrational ideas is so great that even the establishment of a free government would not be able to produce very dramatic results. The establishment of a free government achieves dramatic results only in a culture which, among other things, is prepared to accept science and technology and individual self-responsibility. As I pointed out earlier in this book, this in turn rests on the acceptance of causality, the efficacy of the human mind, and human free will. Only on such a foundation is it possible to develop such vital economic attitudes as: improvement is possible, hard work pays, and the individual has a responsibility to save. At the deepest level, the development of a modern economic system depends on the cultural acceptance of the reliability and efficacy of human reason.⁶⁸

There is a peculiar consequence of the collectivist view of natural resources that deserves mention. I call it the "Argentine delusion," since it is especially prominent in that country. It manifests itself in such statements as: "We are a rich country, but a poor people." And: "We have tremendous wealth. None of our problems are real or fundamental. They're just psychological."

I heard these comments some years ago, when I was in Buenos Aires to give a series of lectures. What the people who made them were referring to is the fact that Argentina is a country of about one million square miles in territory, lying in a latitude comparable to that of the United States, and full of rich farm land and all kinds of mineral deposits. These people believed that somehow

this automatically made Argentina rich, and that nothing could change that fact—not high taxes, not destructive labor unions, not extreme protectionism, not even hyperinflation.

The comments were made to me in Buenos Aires, where these people lived and worked. It is obvious that the speakers would have felt very differently if Buenos Aires had been a separate country, politically independent of the rest of Argentina. In that case, they would not have thought of counting the alleged wealth of Argentina as "theirs" in any sense. Yet if Buenos Aires had been a separate country and maintained mutual free trade with the rest of Argentina, including the ability of individuals in the two areas to come and go as they wished and to do business on the same terms as before, the real benefit of all those resources to the citizens of Buenos Aires would have been exactly the same.

The truth is that Argentina's natural resources do not make her a "rich country." They might make some individual Argentines or foreigners rich—i.e., whoever their private owners are or would be—but the only ways in which they could make the average Argentinean rich would be insofar as their development increased the demand for Argentine labor and thus raised Argentine wage rates, and insofar as their use in production increased the supply and lowered the price of various products. This latter benefit, of course, would be enjoyed not only by the citizens of Argentina but by all buyers of the products concerned throughout the world, no matter what their nationality.

Unfortunately, the policies of the Argentine government prevent both domestic capital accumulation and foreign investment, and thus make the more extensive development of Argentina's natural resources impossible. Thus, in the delusion that they are somehow automatically rich, irrespective of the policies that their government follows, the Argentine people are likely to remain relatively poor. Given their mentality, the natural resources of their country are actually a *liability* to them: in being regarded as an automatic guarantee of wealth, no matter what their government does, the resources make it that much easier for them to allow the bad policies to go on.

Buenos Aires and the other cities of Argentina might actually be more prosperous as independent city states, devoid of all territorial sovereignty over natural resources, than as part of Argentina, with all of its alleged wealth. In such a case, they might realize that the only thing they had to rely on was the industry of their people and that everything they received had to be paid for, even if it came from the surrounding territory. The loss of the delusion of automatic wealth because of territorial sovereignty over natural resources might make them address their problems seriously and thus establish conditions in

which people would be more highly motivated to work and save than is now the case. If that were so, then they could obtain whatever natural resources and agricultural products they required either from the surrounding territories or from anywhere else in the world that offered better terms. Then, perhaps, with a new mentality that recognized the value of a free government, they might look about and see the opportunities awaiting if the neighboring countryside were opened up to free development. They might then reextend their sovereignty into the neighboring countryside and, in effect, reconstitute Argentina on the basis of a free government. Then and only then—under a free government, with full respect for private property rights—would the resources of Argentina finally realize their potential as a source of prosperity, both to the citizens of Argentina and to people all around the world.

The point here, of course, is not to urge the actual breakup of Argentina, even temporarily, but only to highlight the need to shatter the collectivist delusion of automatic wealth through sovereignty over natural resources, and the need to establish a free government in Argentina and in every other country where this collectivist delusion exists.

This section has shown that just as it is not necessary for people to own means of production in order to get the benefit of them, so long as they are free to buy the products of the means of production, so it is not necessary for a country to have sovereignty over any foreign territory so long as its citizens are free to purchase the products of that territory. Indeed, it has shown that the only legitimate interest of the citizens of one country in the territory of another is that it have a free government and thus that its land and natural resources be open to settlement and development by all and that they and their products be purchasable by all. In that way the whole rest of the world derives the maximum possible benefit from the territory of a country without having to have the least degree of sovereignty over it. Thus, a world comprised of capitalist countries would lack any rational economic motive for extensions of sovereignty or for wars of aggression.

In connection with this discussion, the doctrine was refuted that the development and exportation of natural resources by foreigners constitutes an exploitation of the people of a country. It was shown, on the contrary, that such activity is the basis of a higher demand for the labor of a country's citizens and the ability of its citizens to import products of other countries' natural resources as well as products of modern technology. It was also shown how the freedom of foreign investment would operate rapidly to modernize backward countries and raise their

standard of living, if only the governments of those countries would allow investors to profit from the existence of low wages in those countries.

PART B

ECONOMIC INEQUALITY

1. Economic Inequality Under Capitalism

The influence of the division of labor on the institution of economic inequality is almost totally ignored. The views that are typically expressed concerning economic inequality would be plausible only if they referred to a non-division-of-labor, precapitalist society. Thus, typically, people take for granted the validity of such statements as “the rich get richer and the poor get poorer,” and the more fundamental proposition that “one man's gain is another man's loss.”

Now these propositions rest on the assumption that the total wealth that exists in the world, or which can be produced, is a fixed, static sum. Only on that assumption could it be true that one person's gain necessarily implied an equivalent loss by others. Only then could it be true that an increase in the wealth of the rich necessarily implied a corresponding decrease in the wealth of the poor.

Yet this assumption of a fixed, static amount of wealth that can be produced is clearly incorrect in the context of a division-of-labor society. In such a society, a growing body of technological knowledge, manifested in ever improved tools and machines and in man's growing power over the physical world in which he lives, makes possible a continuous increase in the sum total of what is produced. Where the total of what can be produced expands, it is simply false to conclude that one man's gain implies another man's loss, or that the greater wealth of the rich implies the greater poverty of the poor.

Indeed, these propositions are false even in the context of a non-division-of-labor society, so long as conditions are present that make possible an increase in the total of what is produced. To take the simplest and most obvious kind of case, imagine that initially Robinson Crusoe and Friday are each able to gather 10 coconuts a day on their desert island. And now Crusoe, say, devises a pole that enables him to bring down coconuts from higher up in the trees, so that from now on he is able to gather 20 coconuts a day. Crusoe's gain is certainly not Friday's loss. In fact, his gain is almost certain to be followed by Friday copying his new method and thus being able to gather more coconuts of his own. In other words, Crusoe's gain will bring about a gain to Friday, as well.

This little example, it should be realized, also illustrates the absurdity of viewing matters in terms of a “distribution” of wealth and income and then complaining that the “distribution” is unfair insofar as it is unequal. When Crusoe increases his production from 10 coconuts a day to 20 coconuts a day, his “share” of the “national income” of his island rises from one-half to two-thirds. Now Crusoe receiving half of the island’s income is just, according to the egalitarians. But his receiving two-thirds is inherently unjust, according to them. Yet Crusoe’s larger “share” is nothing but the result of his increasing his production.

In opposition to the egalitarians, it should be realized first of all that there is no actual *distribution* of wealth or income here—that a “distribution” exists only in a purely mathematical sense. What actually exists is separate individuals producing different amounts of wealth. When we add up their separate outputs, we reach a sum, and can mathematically express each individual’s production as a percentage or “share” of the total and in this sense speak of a “distribution” of wealth and income. But there is no actual distribution in the sense of someone handing out more to Crusoe and less to Friday. In the same vein, there is no one who makes Crusoe “overprivileged” and Friday “underprivileged.” What each has is the result of what each produces. And, of course, to have what one produces, however great, is a matter of right, not privilege.

It follows from this discussion that what egalitarianism implies is that it is unjust for one person to produce more than another, even if that other not only does not lose, but in fact gains as a result of it. Egalitarianism rests on a mentality that actually ignores production and the ability to increase it. In the manner of a backward child, it assumes that everything comes miraculously from some kind of father, who distributes it this way or that way—fairly, if equally; unfairly, if unequally. It wants the government to compel the father to distribute wealth equally or for the government itself to become the father and distribute it equally.

Now it cannot be stressed too strongly that in a division-of-labor society, one person’s gain is not only not other people’s loss, but is *other people’s gain*.

The most fundamental and important instance of this kind, however much it may shock the egalitarians, who typically depict business as the domain of “robber barons,” is *precisely the building of great business fortunes*. Both in their origin and in their use, these fortunes are a source of gains to everyone who participates in the economic system.

Such fortunes originate in the earning of a high rate of profit on capital, almost all of which is constantly reinvested, so that the high rate of profit rapidly com-

pounds. The fortunes emerge as the sum of the reinvestments of these compound profits over a period of many years. For example, to go from an initial investment of, say, \$100 thousand to \$100 million, requires that one earn a very high rate of profit on the \$100 thousand, save and reinvest almost all of it, and then repeat the same process over and over again for a considerable number of years. Only in this way, through the combination of earning a high rate of profit and saving and reinvesting the far greater part of it over a protracted period of time, can one possibly transform a sum such as \$100 thousand into \$100 million. This is a matter of simple financial arithmetic.

Now as explained in Chapter 6, to earn a high rate of profit requires that one be a leader in the introduction of new and better products, in improving the methods of producing existing products, or in meeting changes in consumer demand inaugurated, for the most part, by economic progress.⁶⁹ And, as also shown in Chapter 6, because competitors copy innovations as fast as they can and try wherever possible to supersede them, with the result that the profits from any given innovation tend steadily to disappear and be replaced by losses, the earning of a high rate of profit over a long period of time requires that one *repeatedly* be a leader in innovation. *Thus, the high profits out of which great fortunes are accumulated are the result of repeatedly introducing improvements in production.*⁷⁰

These improvements, of course, represent better and less expensive goods for the general buying public. They thus represent a rise in the real income of everyone—everyone benefits in his capacity as a buyer. This is what I mean by the statement that in their origin great business fortunes are a source of gains to all.

What I refer to in the statement about the general gains great business fortunes represent in their use is simply the fact that the fortunes are invested: they represent factories, machines, inventories and work in progress, and the means of paying wages and salaries. Here again they are the base of additional goods coming to market and thus of gains to all buyers; in addition, they provide greater financial means for people to be buyers—insofar as they are the source of a greater demand for labor and thus of additional payments of wages and salaries.

Thus, in a division-of-labor, capitalist society, the accumulation of a great fortune is the mark of great contribution to general human well-being.

This principle is readily confirmed by an examination of the history of great fortunes in the United States. To take two leading examples from the age of the so-called robber barons, both Henry Ford and John D. Rockefeller began their careers in industries that were relatively small and backward. They devoted their lives to search-

ing out and implementing all manner of improvements in those industries, on the basis of which they earned very high rates of profit, almost all of which they saved and reinvested. At the end of their lives, the industries in which they worked were enormously improved and expanded because of their efforts, and their wealth was embodied in the means of production of those industries.

Thus Ford increasing his capital from approximately \$25,000 in 1903 to approximately \$1 billion at the time of his death in 1946, was the result, and, indeed, the measure, of his introduction of one major improvement in automobile production after another, such as the use of moving assembly lines and interchangeable, mass-produced parts, and his use of the profits he made thereby to pay for the construction and equipping of one major automobile plant after another, each embodying the improvements he introduced. Similarly, Rockefeller's fortune was founded on the introduction of improvements transforming the petroleum industry from the backward, inefficient production of kerosene into the highly modern, efficient production of a whole range of petroleum products previously unheard of. It was also based on his pioneering in the ability to use petroleum deposits that were previously unuseable—by virtue of the development of such innovations as refineries capable of chemically cracking petroleum molecules. Rockefeller's billion was the measure of the improvements he introduced and of his continuous reinvestment of the profits resulting from those improvements. It was embodied in a host of modern oil refineries and pipelines, which did not exist before him and might very well never have come into existence without him.

Andrew Carnegie and Commodore Vanderbilt played comparable roles in the building of the American steel and railroad industries. Many great industrialists made great fortunes. As far as the fortunes were made in a free market, the essential principle underlying all of them was a process of repeated productive innovation and the reinvestment of the far greater part of the resulting profits. As the result of such fortune building, the American people obtained an increasingly more modern and more efficient economic system, from which they all greatly benefitted in their capacity as consumers and as wage earners. From the perspective of the general public, whatever people may have mistakenly believed, the *objective* significance of the fortunes was new and better products, new industries, and lower prices relative to wages. The gains of the great industrialists—the so-called robber barons—were overwhelmingly the gains of everyone who bought their products—or even the products of competitors, who were forced to meet the standard they set. Their gains were also the gains of everyone whose wages were increased by the additional

demand for labor their savings created. Their wealth represented an enormous net increase in the total wealth of the economic system and was the source of a correspondingly great increase in the standard of living of the average person, since it served to increase the production and supply of products he could buy and the demand for the labor he wished to sell. These men were among the greatest innovators and accumulators of capital of all time, and everyone benefitted enormously from their success. They were neither robbers nor barons, but in the highest rank of capitalist producers, whose great self-enrichment was the measure of their enrichment of the general public. They did not steal their wealth but created it, in the process greatly enriching others, not impoverishing them. They were in fact among the greatest benefactors of mankind in all of history.

Consistent with the preceding discussion, in appraising the so-called distribution of wealth—that is, distribution in the sense of who owns what percentage of the total capital that is invested in the economic system—one should keep in mind the following essential facts. Namely, in a division-of-labor, capitalist society there are basically two elements determining such “distribution.” These are the relative amounts of income people earn and the relative degrees to which they save and invest those incomes.

In the case of large accumulations of wealth, the relative amount of income one earns typically reflects the relative rate of profit one earns on one's capital. Basically, those individuals have the greatest accumulated wealth who earn the highest rates of profit and save and invest the greatest percentage of their profits. Thus, for example, an individual who earns a 25 percent annual rate of profit and saves and reinvests 80 percent of his profit increases his capital at a 20 percent compound annual rate. In contrast, an individual who earns a 3 percent annual rate of profit and consumes all of it does not increase his capital at all. By the same token, an individual who earns a zero rate of profit and consumes at an annual rate of 3 percent of his capital steadily depletes his capital; and if he incurs actual losses, he depletes it all the faster.⁷¹ Thus, it should be clear that relative rates of growth or decline in accumulated wealth are the result of a combination of relative rates of profit and relative degrees of saving out of profits.

In both of these respects, the accumulation of wealth under capitalism is the measure of contribution to the economic well-being of the rest of society.

To the degree that businessmen and capitalists earn relatively high rates of profit, it is because they are in the forefront of introducing better products and better methods of production and in reshaping the economic system

to adapt to changes in demand originating mainly in economic progress.⁷² To the degree that they save and invest a higher percentage of those profits, then along with increasing the economic system's degree of capital intensiveness and thus receptiveness to technological progress, they increase both the demand for capital goods relative to the demand for consumers' goods and wage payments relative to the personal consumption spending of businessmen and capitalists as a class.⁷³ The higher relative demand for capital goods leads to a correspondingly greater concentration on the production of capital goods in the economic system and thus to a more rapidly growing supply of capital goods, which is a critical factor in raising the average productivity of labor and thus real wages.⁷⁴ And the increase in wage payments relative to the personal consumption spending of businessmen and capitalists enables wage earners to enjoy a larger proportion of the overall consumption spending that does take place, which also serves to raise real wages.⁷⁵ In all these ways, inequality in the so-called distribution of wealth is an essential aspect of a high and rising absolute amount of wealth that is available to the average person under capitalism, in particular to the average wage earner.⁷⁶ It is thus the measure of the individual's relative productive contribution to general economic well-being.

Mutuality of gains—one man's gain being other men's gain—is inherent in the very nature of a division-of-labor, capitalist society. It is inherent, first of all, in the fact that in such a society, cooperation takes place by means of exchanges, which are strictly voluntary and entered into only in the expectation of gain by both parties. In an exchange, each party gives only in order that he may receive something he values more. Unless both parties expect to gain by it, an exchange does not take place.

The objective foundation underlying mutual gains from exchange as an everyday, common occurrence—as a virtually omnipresent phenomenon—is the division of labor. Its existence ensures that gains are in fact available for all. For the division of labor raises the average productivity of labor and allows it and the total of what is produced to go on rising, without limit. At the same time, of course, it places every individual in a position in which he must exchange the overwhelmingly greater part of his goods or services for all the things that he himself does not produce and which others produce.

The progressive rise in the productivity of labor and the mutual gains from exchange are two aspects of the process by which one man's gain becomes the gain of others in a division-of-labor society. A third aspect, present, as we saw, even in the context of Robinson Crusoe and Friday on their desert island, is the copying of others'

success. This last aspect is present in a division-of-labor society in the competitive quest for high profits, which constantly operates to deprive every innovation of its special profitability and to require fresh innovation as the means of maintaining a high rate of profit. It is equally present in the competition of wage earners for higher-paying jobs. As explained in Chapter 6 of this book, it is the element that, in the absence of further changes, operates to drive the rate of profit on capital invested toward uniformity in all branches of industry and the rate of wages for all workers of the same degree of skill and ability toward uniformity in the same labor market.

Indeed, as the example of Crusoe and Friday and their coconuts suggests, and as the tendencies toward uniform rates of profit and uniform wages for workers of the same degree of ability suggest, economic inequality in a division-of-labor, capitalist society can be understood as resting on an inequality in productive ability that is dynamic in several senses. The inequality in productive ability is dynamic in one sense in that those of outstanding ability succeed in steadily raising the productivity and real remuneration of those of lesser ability. It is dynamic in a second sense in that at each level of ability, it reflects uneven contribution or adaptation to the process of improvement. Finally, it is dynamic in that there are no legal barriers to individuals crossing over from one level of ability to another.

Thus, businessmen and capitalists have greater income and wealth than wage and salary earners. But their innovations and capital accumulation raise the productivity and remuneration of the wage and salary earners, and do so continually. Among businessmen and capitalists and among each grade of wage and salary earners, there are further inequalities that reflect uneven contribution or adaptation to the process of improvement. That is, there are businessmen and capitalists who earn very high rates of profit because they introduce innovations or adopt them relatively early, and there are others who earn low rates of profit or suffer losses because they lag too far behind in the adoption of innovations. Similarly, there are wage earners who earn relatively high wages because they adapt their skills relatively quickly to the kinds of labor being demanded for the implementation of the improvements introduced by the businessmen and capitalists, and, by the same token, there are wage earners who earn relatively low wages because they fail to adapt their skills quickly enough to the process of improvement. Finally, wage earners are always legally free to become businessmen and capitalists, and unsuccessful businessmen and capitalists are always being reduced to the ranks of the wage and salary earners. Indeed, there is constant movement up and down within and between all economic strata.

On the basis of all of the foregoing, it should be clear that the economic inequality that exists in a division-of-labor, capitalist society is an inequality in which the greater success of some is the cause not of the failure of others, but of their success too. It is in its most important respects simply an inequality of success and progress—an inequality in which some are merely further ahead than others on the road of improvement. The inequality of such a society is an inequality in which the “rich” and the “poor” *both* grow richer, and in which the classification of any given individual as belonging to the class of the “rich” or the “poor” is constantly subject to change by virtue of his own efforts and abilities.

This discussion, of course, provides the answer to those who make such complaints as that under capitalism 10 percent of the population owns 90 percent of the “wealth” (i.e., the capital) of the country. Even if the claim were accurate, there would be absolutely nothing wrong with such a situation. It would not be the result of wealth being unfairly “distributed.” It would be the result of some people contributing more to production than others—in the more important cases, introducing a series of major improvements into production, and then saving and investing very heavily out of the higher incomes they earned. The 90 percent of the wealth that is not only owned but also *created and earned* by the 10 percent who own it (or by their parents or grandparents), would then serve the 90 percent of the population that did not contribute as much to production. Because of the freedom of the 10 percent to create and earn the wealth and income they do, there is incalculably more wealth: there is more saving and the means of production that exist at any given time are more efficiently used, both of which facts are causes of the continuous further increase in the supply of means of production—of capital goods—that, as we have seen, are used to produce overwhelmingly for the benefit of the 90 percent of the population that allegedly owns only 10 percent of the wealth of the economic system.

For the 90 percent to seek to steal the wealth of the 10 percent is to destroy the creation of the wealth that serves them. It is to begin with no concept of the production of wealth and how it is accumulated, but instead with the myth of the “distribution fairy,” and from there to go to envy and resentment, from there to theft, and with theft, to the destruction of the incentives to saving, efficiency, and the accumulation of capital. The result is that those whose heads are empty of the knowledge of how wealth is produced and accumulated come to live in a world that is physically empty of the production and accumulation of wealth. Once having become maliciously ignorant thieves, they go on to end as starving wretches.

2. Critique of the Marxian Doctrine on Economic Inequality

On the basis of what has been established concerning the nature of economic inequality in a capitalist society, it is now possible to grasp the enormity of the injustice that Marxism and its supporters have perpetrated in connection with this subject.

According to Marxism, the inequality between capitalist and worker is essentially no different than the inequality that prevailed in earlier periods of history between master and slave or between lord and serf. All of history, declares Marxism, is the record of one continuous class struggle that has been carried on in different forms and under different guises. In the Ancient World, it was between master and slave; in the Middle Ages, between lord and serf; today, it is allegedly between capitalist and worker. The worker of capitalism, says Marxism, is also a slave—a “wage slave.” And the capitalist is an “exploiter” even more ruthless than the feudal lord or ancient slave owner. For capitalism, says Marxism, cannot even “assure an existence to its slave within his slavery,” but compels the worker to sink ever deeper into poverty and starvation.⁷⁷

Mankind’s only salvation from exploitation and class conflict—its only hope for elevation into a new world of peace and harmony—Marxism declares, is the establishment of socialism. Socialism, it claims, holds out the promise of a classless society, free of all exploitation and conflict—a society of perfect equality. In achieving the equality of wealth and income, it will allegedly complete the work of the so-called bourgeois revolutions of the eighteenth and early nineteenth centuries that established representative government and political equality.⁷⁸

These doctrines permeate the contemporary educational system—in history books, in so-called social-science courses, in literature courses, in every field and in every way in which it is possible to inculcate them.

Every aspect of the Marxian doctrine on inequality is false and vicious.

The Marxian doctrine claims to see as essential the mere existence of inequalities in wealth and income, absolutely irrespective of their nature and cause. It ignores the radical, day-and-night difference between economic inequality under capitalism and economic inequality under serfdom and slavery. Specifically, what it ignores is the fact that under capitalism economic inequality rests on *differences in productive contribution*, which contribution operates to the benefit of all. Those who have more under capitalism have it because they contribute more to production (or because their parents or grandparents did), and their contributions enable everyone else to have more also. In other words, the greater wealth and income

of the capitalists and of the higher-paid wage and salary earners is *earned*, and the process of earning it is the source of *general benefits*.

The greater wealth and income of a feudal lord or of a slave owner, on the other hand, was of an entirely opposite character. It was obtained not by means of any productive contribution on his part, but by means of *physical force*—essentially by theft and extortion. As such, his gain really was the loss of others: what a robber steals, his victim loses.

The Marxists seek to evade having to acknowledge the difference between a capitalist and the owner of serfs or slaves by means of an equivocation on the use of the word “force.” The owner of serfs or slaves obviously uses force or the threat of force against them. But, ask the Marxists, isn’t the fact that reality compels a man to work if he would eat, not also a kind of force? And isn’t it force that, for all practical purposes, a worker must work for a capitalist, unless he is in the exceptional position of having a substantial amount of savings of his own? Thus aren’t the workers “forced” after all to work for the capitalists?

Such ideas are expressed in a more subtle form by John Kenneth Galbraith in his book *The New Industrial State*:

The worker in a Calcutta jute mill who loses his job—like his American counterpart during the Great Depression—has no high prospect of ever finding another. He has no savings. Nor does he have unemployment insurance. The alternative to his present employment, accordingly, is slow but definite starvation. So though nominally a free worker, he is compelled. The fate of a defecting southern slave before the Civil War or a serf before Alexander II was not appreciably more painful. The choice between hunger and flogging may well be a matter of taste.⁷⁹

The essential point Galbraith seeks to make in this passage is that the distinction between freedom and slavery is nominal if a worker must work in order to avoid starvation. This idea is absolutely vicious. It is straight out of the world of *1984*: it claims literally that freedom is slavery. It is a repetition of the apologetics for slavery offered in the South before the Civil War and more recently by the supporters of Soviet Russia.

The difference between freedom and slavery is as sharp as day and night, even when a worker must work to avoid the pain of hunger. For even in this case it is not the capitalist employer who *causes* the worker’s hunger. On the contrary, he provides the means of *satisfying* the worker’s hunger. The worker works for the capitalist always in order to receive a positive—his wages. The difference between a free worker and a slave can always be seen in this: A slave is someone who is kept at his work against his will: by chains, whips, and guns—i.e., by physical force applied by other people. In the absence of

such things, he would run off. A free worker, on the other hand, is someone who works of his own choice and who, more likely, can be *kept from* his work only by means of physical force. The worker in Galbraith’s Calcutta jute mill, for example, is not kept there by the threat of being shot if he leaves, as is the case of a worker in a Communist or Nazi labor camp. On the contrary, from Galbraith’s description, it is probable that it would take the threat of being shot to keep that worker away from his job.

A worker is a slave not because he must choose to work as the means of eating, but when he chooses *not* to work and is compelled to do so nevertheless—by means of physical force. Of course, very few people can choose not to work at all for very long. But no matter how poor they are, they can always choose not to work for any *particular employer*, whenever any other employer offers them better terms. This fact, that while people must work in some capacity, they can choose *in which particular capacity*, Galbraith and the Marxists choose to ignore, by focusing on the case of unemployment and the unavailability of alternative jobs.

The existence of unemployment and the lack of alternative jobs is itself the consequence of violations of freedom and capitalism—specifically, violations such as prounion and minimum-wage legislation, which keep money wages artificially high relative to the demand for labor.⁸⁰ Yet even though mass unemployment exists, it does not prevent individuals from having alternative employment opportunities at some time or other in their lives. And the ability to choose among these alternatives is vital. Its importance to the individuals concerned is demonstrated by the fact that to deprive them of it, chains, whips, and guns are required.

So much then for the attempt to portray capitalist employers as slave or serf owners, on the basis of an equivocation between forced labor and the necessity of working imposed by the nature of reality.

By the same token, it should also be realized that slave and serf owners qua slave or serf owners did not at all derive their incomes in the manner in which a businessman or capitalist derives his. They did not, for example, derive their incomes by virtue of owning land or capital—the means of production. They derived their incomes by means of the initiation of force—by extortion and theft. It is necessary to clear up this confusion particularly in regard to feudal aristocrats, who, it is often assumed, held their position on the basis of their ownership of large tracts of land.

The feudal nobility were in fact not landowners at all in the proper sense of the term. Their position was more analogous to that of hereditary commanders of military bases. As mentioned earlier in this chapter, a feudal

nobleman did not have the right to sell his alleged property, or to pledge it as security for debt, or to contract away its use on a long-term basis. For the theory of feudal landholdings was that the land was intended to serve an unbroken line of succeeding generations of noblemen. Each of these would use it in part to maintain himself and his family at a level dictated by custom, and, for the rest, to maintain vassals, with whom he would appear at the side of the king or some other higher nobleman when called upon to do so. And the king himself was not to regard his domains as his private property, serving his personal pleasure, but as serving the purposes of the state.

The feudal nobleman both lacked essential rights of a private property owner and possessed powers that are absolutely no part of the rights of a private property owner. For all practical purposes, *he was the local government*: he combined in his person the powers of policeman, judge, and lawmaker. His workers were legally prohibited from leaving his estate. By the same token, no other nobleman was allowed to bid for the services of his workers.

Thus, a feudal nobleman did not earn his income in the manner of a landowner or capitalist, who must compete for labor, and who holds his position only by being able successfully to compete as a seller in the market for products as well. Rather, he derived his income in his capacity as a virtual slave owner and as a tax collector.

Consequently, every aspect of Marxism's attempt to confuse economic inequality under capitalism with economic inequality under earlier systems is false. The greater income and wealth of the businessman and capitalist is the result of their positive productive contribution, which increases the income and wealth of everyone else as well; while the greater income and wealth of the owner of slaves or serfs is based on force and is thus at the expense of the income and wealth of everyone else. It is economic inequality based on positive productive contribution and resulting in general benefit, versus economic inequality based on force and resulting in others' corresponding loss. That is the difference between economic inequality under capitalism and economic inequality under slavery and serfdom.

Ironically, the difference between the economic inequality of capitalism and that of slavery and serfdom is no less the difference between the economic inequality of capitalism and the economic inequality of *socialism*. Socialism, we have seen, is itself, both in fact and by its very nature—both economically and morally—a system of aristocratic privilege and of systematic exploitation of the masses by a ruling elite. It renders the ordinary citizen economically powerless by establishing the state as a universal monopoly employer and, at the same stroke, by

destroying the incentive of profit and loss and the freedoms of individual initiative and competition in the production of goods. Morally, it demands that the individual live not as an end in himself, as he does under capitalism, but as a means to the ends of "Society," which, of necessity, means that he live as a means to the ends of the rulers, who divine the ends of "Society."⁸¹

In no sense is socialism some kind of extension into the economic sphere of the noble principles associated with the words political democracy, or, more accurately, political freedom—as many people believe in naively repeating this popular Marxist theme. On the contrary, it constitutes the total destruction of all political freedom along with all economic freedom. As I have shown, socialism is necessarily a system of totalitarian dictatorship.⁸²

Thus, virtually every evil that the socialists allege of capitalism on the score of economic inequality, while not true of capitalism, is true of socialism. By the same token, the end of exploitation and the achievement for the first time in human history of a society based on the peaceful, harmonious cooperation of all men, which the socialists allege will come with the arrival of socialism, has already come—to the extent of the arrival and continued existence of *capitalism*.

Economic Inequality and the Law of Diminishing Marginal Utility

The attempt is sometimes made to support the advocacy of economic equality on the basis of the law of diminishing marginal utility. Such writers as Oscar Lange and other socialists argue that any given-sized unit of wealth has a higher marginal utility to whoever has fewer such units.⁸³ They argue, for example, that \$1,000 has a higher marginal utility to a man who is worth only \$10,000 than to a man who is worth \$100,000. It follows, they believe, that if \$1,000 were taken from the man with \$100,000 and given to the man with only \$10,000 an increase in total marginal utility would result.

In their view, the law of diminishing marginal utility implies that some kind of gain in utility can be achieved so long as anyone has more than someone else and his wealth can be transferred to a party who has less: the marginal utility of the wealth gained by the poorer person will allegedly be greater than the marginal utility of the wealth lost by the richer person. Perfect equality of wealth and income appears to them to be a norm requisite for maximizing "utility"—in a country or in the world. Needless to say, this argument serves as an important rationalization for the progressive income and inheritance tax and for other forms of confiscation of wealth and income.

It is difficult to say which is the greater defect of this

argument: the lightness with which it takes the matter of property rights and the speed with which it is prepared to violate them, or its confusion concerning the nature of marginal utility. The argument assumes that all that has to be established is that something is wanted or needed by someone more than by its owner, and that that is sufficient to justify forcibly taking it from its owner and giving it to the nonowner.

That this is what the argument assumes is highlighted if we put aside any question of inequality of wealth or income for the moment, and consider the vast range of other cases in which something can have a higher marginal utility to someone who does not own it than to the person who does own it. Thus, for example, if anything, whether a painting or a puppy, is owned by someone who does not appreciate it or therefore value it as highly as someone else would who does not own it, the argument of the socialists concerning diminishing marginal utility implies that a *prima facie* case exists for taking the property from its owner and giving it to the other party. For this change in ownership too will allegedly result in an increase in total marginal utility. Thus, the argument implies not only that a poor person has a right to the property of those who are better off than he is, and who therefore need it less. It implies equally that anyone who would value something more highly than its present owner, whether on the basis of his education, character, or whatever, as much as on the basis of the smallness of the number of units he owns, has a right to it at the expense of the owner.⁸⁴

The supporters of this view, it should be clear, have no regard for rights of any kind, but merely for needs and desires. They have never outgrown the chaotic world of small children, who frequently act on the principle that whoever needs or wants something has the right to take it away from its owner, irrespective of the owner's wishes. The only difference between them and such children is that they think it must be clear that they, or some other beneficiary, need the goods *more* than the owner before they seize them and that they use the government to seize the goods rather than seize them personally.

This brings us to the other fundamental defect of the argument for economic equality on the basis of the law of diminishing marginal utility. This is the fact that it divorces the concept of marginal utility from individual people and assumes that it pertains to a kind of collective organism, of which the individuals are mere cells serving as centers of pleasure and pain for the organism. It is only on this basis that it can be assumed that the loss of a thousand dollars by one person and the gain of a thousand dollars by another person represents any kind of overall net gain. The argument assumes that the individuals are mere cells of "*Society*," which allegedly feels only a

relatively small loss when the richer person's wealth is diminished and a relatively great gain when the poorer person's wealth is increased.

Of course, the problem with this view of things is that people are not cells of some greater organism. Each *individual person* is an organism. Thus, each individual person constitutes a separate base and standard for judging utility. It is only *to the individual human being* that there can be utility, marginal utility, or any other kind of value.⁸⁵

It is true that *to one and the same person* \$1,000 would be of higher marginal utility if all he had was \$10,000 than if he had \$100,000. But it is a non sequitur and completely false to imply that the marginal utility of \$1,000 to this individual is increased if, when *he* has \$100,000, \$1,000 is taken away and given to *someone else*, who has only \$10,000. It is absurd to think that the eleventh \$1,000 in the hands of someone else is of greater marginal utility to a person than the one-hundredth \$1,000 in his own hands. And if it is not the marginal utility to *this person*, the man who has the \$100,000, that is increased, then there is no universal, objective, or valid sense in which marginal utility could be increased by "redistribution." Exactly the same point applies to "redistribution" in favor of those who appreciate and value things more highly on the basis of factors other than the smallness of the number of units they possess. It is no satisfaction to someone whose painting has been stolen that now it is in the collection of someone who looks at it more often and with greater pleasure than he, the owner, would. The most intense pleasure of the thief is of no account to the owner.

The fundamental philosophical issue that is present here is the conflict between altruism and egoism. Altruism demands that we regard the needs of others as though they were our own. If we were starving, we would value a bowl of rice as highly as our lives. Asiatic coolies and others *are* starving, and thus, according to altruism, we should be as concerned as if we ourselves were starving. Nevertheless, in fact, we value our last scoop of ice cream or bar of chocolate above their first bowl of rice, which rice we could buy for them with the price of the ice cream or chocolate, if we chose.

According to altruism, such a state of affairs is a moral abomination, and we deserve to feel profoundly guilty for allowing it to exist. Many of us, no doubt, do feel guilty for a while, when the plight of the coolies or other impoverished, suffering group is called before us; but our guilt rarely lasts so long or goes so deep that we are led to give up very much for the sake of such groups. We find that giving charitable assistance is also of diminishing marginal utility, just like any other activity, and we leave off at a point where the importance we attach to the

satisfaction of others' needs is far less than if those needs were our own. There is good reason for this. The basic fact is that we are separate, independent organisms, and our survival, well-being, and enjoyment require that each of us devote his abilities to providing for himself.

This does not mean that we are unconcerned with the needs of others. There are some others, such as spouses, children, parents, and close friends, whose existence and well-being are very important to our happiness. We are very much concerned with the needs of these others, and often attach as much or even more importance to providing for their needs as for our own, because we regard their existence and happiness as vital to our own. For example, most parents would rather go hungry themselves than allow their children to go hungry.

Apart from this small number of other people, however, there is no connection between our lives and well-being and the lives and well-being of others that is of such a nature as would justify our expending any major portion of our energies or wealth for their sake. It is true that because of the harmony of rational self-interests that prevails under freedom, and which this book repeatedly demonstrates, we also derive major benefits from the existence, success, and prosperity of others whom we do not know or have any personal relationship with, and, indeed, potentially could each derive enormous benefit if the whole human race were successful, prosperous, and happy. Nevertheless, in the very nature of the case, the good will that we can reasonably feel for the rest of our countrymen and the whole rest of the human race that is founded upon their actual or potential success and prosperity *precludes their being a drain upon us*. This is because our benefit comes from the work and saving they do, which are the source of their success and prosperity along with contributing to our own. To the extent that others are successful and prosperous, of course, they do not need our charity.

Of course, the reasons for desiring to see other people in a state of well-being go beyond purely economic considerations. As rational beings, we practice induction. When we see another human being, we see another creature who in the most fundamental essentials is like us. When such a being is successful and happy, we see a confirmation that we can be successful and happy, and so we feel better as a result. By the same token, when we see another human being who is suffering and in pain, though he has done nothing to deserve it, we see evidence that we ourselves can be threatened, and thus we feel badly. As a result, when people are the victims of natural disasters beyond their control, such as earthquakes or floods, charity can be given in the name of the positive value of seeing them restored to their normal success. By its very nature, however, such assistance both has a

selfish basis and is limited and temporary. It does not represent a blank check. It does not elevate the needs of others into any kind of mortgage on our lives or imply that we must make any form of sacrifice of our own well-being in order to serve them. On the contrary, it is given in the name of our own values and as part of the process of pursuing our own happiness.⁸⁶

In giving such assistance, the values involved for us are the same in nature as those which are involved in literature and drama, where we desire to see "happy endings"—that is, human success—and feel depressed at the vision of human failure. And just as our desire to see the success of human values does not lead us to spend more than a limited amount of time and money on novels, plays, and motion pictures, and so forth, so it does not lead us to devote more than a limited amount of time and money to charitable activities. Just as we find that after a point the marginal utility of all kinds of other goods outweighs the marginal utility of another novel or movie, we find that it also outweighs the marginal utility of charitable contributions.

In the present-day world, the apparent need for charitable assistance enormously dwarfs the self-interest of people in providing it. Over three-quarters of the world's population live in or not far removed from a state of hunger. Even in the richest countries, there are large numbers of people who are unemployed, or who, even if they are employed, are still apparently unable to pay the cost of an education, an illness, or a modest home. If one looks back at the past, the situation was even worse: there were far fewer prosperous people, and those who were considered prosperous had much less.

Charity is obviously impossible as a solution to a problem of poverty on this scale. It can never be to the self-interest of people to attempt the support of so many others to such an extent. Even if, somehow, they were willing to try, they could not succeed.

Nevertheless, most moralists have proceeded as though charity were the solution. And they have vilified people to the extent they were able to prosper and devoted their wealth to the enjoyment of their own lives. They have attempted to make people feel guilty for their success and enjoyment and have tried to take it away, through governmental "redistributions" of wealth and income. The influence of such moralists is entirely destructive. So-called redistribution impoverishes even those whom it is intended to benefit, as should by now be abundantly clear.⁸⁷

The fact that neither private charity nor governmental coercion is the solution to poverty does not mean that there is no solution and that the alternative is simply to accept a world of suffering. On the contrary, we can have a world in which a high and rising degree of human

well-being is the overwhelming norm everywhere. In such a world the cases requiring charity would be so reduced in frequency that they could be provided for within the limits of people's rational self-interest.

The solution to the present problem of massive, overwhelming poverty is nothing other than *the science of economics*. As should be increasingly clear, economics is a science which can make possible the construction of a social and political system in which human success is a feature of normal, everyday life everywhere. It is truly *the humanitarian science*, and only those who have studied it well and who are prepared to implement its teachings deserve to be called friends of mankind. The most important charity which the true friends of mankind can pursue is to disseminate knowledge of this vital subject as widely and as deeply as they know how.

The solution to poverty that economics offers is, of course: *the freedom of the individual*—i.e., laissez-faire capitalism—a system in which each pursues his own good and, at the same time, is necessarily led to promote the good of those with whom he deals, as the condition of obtaining their voluntary cooperation. *This is the engine* for transforming poverty into prosperity. In its effectiveness in overcoming poverty, it surpasses the futile gestures of traditional, altruist morality, which has been handed down unchanged in all essentials since the Middle Ages, on the same scale as the rest of modern civilization surpasses that of the Middle Ages. It is the difference between a rocket ship and an oxcart. Indeed, when one considers the nature of the demands for sacrifice, pain, and suffering, it is the difference between a rocket ship and a medieval torture chamber.⁸⁸

It should be realized that the use of the law of diminishing marginal utility to support the demand for economic equality, is closely related to the doctrine of "external benefits," in that both rest on the obliteration of the individual human being as the base and source of values, and feel free to talk of "utility" or "benefits" apart from the context of specific individuals.⁸⁹ The only difference is that the doctrine of external benefits goes a step beyond the egalitarian version of diminishing marginal utility. Thus, according to its logic, if a painting is stolen from the private collection of a millionaire who does not appreciate it very highly, and is stolen not merely by someone who appreciates it more, but by someone who exhibits it to multitudes of others, many of whom also appreciate it more, then what is present is not only the alleged gain in marginal utility that exists by virtue of the painting falling into the hands of the more-appreciative thief, but also the further alleged gain of the more-appreciative multitude's enjoyment. This last is an alleged "external benefit" of the theft. What is overlooked by the

external-benefits doctrine, of course, is that, like the enjoyment of the thief, the enjoyment of such a multitude, especially if its members are knowing accomplices to the theft, represents absolutely no value, indeed, a negative value, to the victim of the theft, and thus can claim no objective status, certainly no positive moral status.

Precisely such considerations must be raised against the use of the external-benefits doctrine to justify taxation for the sake of such programs as public education. It can be granted that education benefits not only its recipients but also all who come into contact with its recipients. This fact, however, does not justify the support of education by taxation or imply that a free market provides inadequately for education. The combined benefit of education both to its recipients and to those who come into contact with its recipients does not have any existence apart from the lives and purposes of definite, individual human beings. An individual millionaire, for example—the prospective victim of an education tax—can legitimately value his own yacht above all the effects, direct and indirect combined, of other people's children receiving an education at the price of his not receiving his yacht.

True enough, if education lived up to its inherent potential of typically producing civilized adults, instead of, as is the case today, growing hordes of illiterate, semi-savage delinquents, it would indeed represent a major benefit to everyone. It would be the basis of a civilized, flourishing society. And in such circumstances, many people, especially many millionaires, would value the support of education above the purchase of some further personal luxuries. This in fact is why millionaires have traditionally been generous benefactors of education. In so doing, they would serve their own selfish values. They would provide to some significant extent both for the value they attached to living in a civilized society and to passing on such a society to their children, and for the value they attached to their own direct personal enjoyment in the form of such things as yachts.

The external-benefits doctrine, of course, ignores such facts. When it talks of the free market, it takes for granted that the participants are unthinking brutes incapable of understanding or appreciating the wider benefits resulting from such things as education and thus unwilling to support such activities voluntarily. Then, in a still greater affront to the humanity and the human dignity of the individual, it urges the government totally to disregard the choices, the judgment, indeed, the very existence of the mind and person of the individual, and to proceed simply to seize his wealth for use in the support of "external benefits."

What the supporters of the external-benefits doctrine need to realize is that a free market, in the sense of the

arena of all voluntary financial transactions, provides all the funds to which education and all other activities entailing “external benefits” are properly entitled, consistent with the understanding and values of the citizens. Even more importantly, they need to realize that an essential precondition of the existence of any objective value of external benefits is that those who are to finance them not be regarded as sacrificial victims. An indispensable precondition of the pleasure or enjoyment or any other kind of value to others being a value to an individual is respect on the part of those others for his individual rights and his free judgment, including, of course, his free judgment with respect to the use of his own property. Nothing represents an external benefit to an individual if his sacrifice is required to achieve it. No gain to others is a gain to an individual insofar as those others regard him as a sacrificial animal. Thus, the external-benefits doctrine, as an attempt to wring benefits for others from sacrificial victims, by means of force, destroys the very foundation of the existence of benefits to others being a value to an individual. The doctrine is thus a self-nullification.

Further, when applied to education, the doctrine is a twofold self-nullification. For it introduces into the very foundation of education the preschool principle of uncivilized small children that the mere fact of wanting something entitles one to seize it, irrespective of the will—irrespective of the mind—of the owner. Education supported on the principles of the external-benefits doctrine is the self-contradictory monstrosity of education without respect for the human mind. It is the self-nullification of education that is visible above all in today’s system of public education.

Economic Inequality and the Normal Curve

The widely-used economics textbook by Samuelson and Nordhaus claims that economic inequality cannot be explained on the basis of inequalities of ability. It declares: “People differ enormously in their abilities However, these personal differences provide us with very little of the answer to the puzzle of income dispersion.”⁹⁰ In support of this claim, the authors observe: “Abilities are much more equally distributed than are incomes While human traits seldom differ by more than a factor of 3, high incomes today are more than 100 times greater than the lowest.”⁹¹

The meaning of these words is that economic inequality has little or nothing to do with ability, inasmuch as the “distribution” of income does not follow the pattern of distribution of ability. Abilities, Samuelson and Nordhaus point out, such as those measured by IQ tests, follow the pattern of frequency distribution described by the normal curve.⁹² The normal curve is a bell-shaped curve

whose mean value, represented by the apex of the curve, is the most frequently occurring value. Additional properties of the normal curve are that the deviations above and below the mean occur both equally and with more rapidly diminishing frequency the greater is their departure from the mean. In a normal distribution, over 99 percent of all occurrences lie within the limit of plus or minus three standard deviations from the mean value. Thus, for example, in the case of IQs, the most frequently occurring IQ is 100, and approximately as many people have IQs above 100 as below 100, with more than 99 percent of the population having IQs between 50 and 150, that is, between values respectively equal to half and one-and-a-half times the mean value.

Apparently, according to the logic of Professors Samuelson and Nordhaus, what would be necessary for intelligence to be the explanation of inequalities of income would be if the earnings of those with IQs of 150 were only three times as high as those with IQs of 50, rather than one hundred or more times as high—in other words, if the earnings of geniuses were only three times those of morons, rather than a hundred or more times those of morons. In that case, inequalities of income would show the same pattern of dispersion as inequalities of intelligence. Indeed, it is logically implicit in the position of Professors Samuelson and Nordhaus that for inequalities in income to be based on inequalities in intelligence and ability—that is, to meet the requirement of similarly conforming to the normal curve—either morons must be capable of performing such activities as brain surgery one-third as frequently as brain surgeons perform it, or the work that morons can do must be one-third as valuable as the work brain surgeons do—and similarly in comparison with others whose abilities are greater and rarer even than those of brain surgeons. If neither of these conditions is met, that is, if morons cannot perform such activities as brain surgery at all and if brain surgery and the like are substantially more than three times as valuable as the work morons can do, then according to Professors Samuelson and Nordhaus, inequalities in income cannot be based on inequalities in intelligence and ability; they allegedly cannot, because if they were, they would be normally distributed, just as are the inequalities in intelligence and ability.

Of course, none of the above is a claim on my part that intelligence is the only factor which determines the relative income and wealth of individuals. (Nor is it to say that what is today considered intelligence necessarily embraces all aspects of intelligence or gives them their proper weight.) In order for greater intelligence to result in the earning of higher income and greater wealth, it must be accompanied by such factors as rationality, ambition, hard work, and forethought, and, in addition,

the valuation of more income and wealth above alternative goals. If it is accompanied by the necessary further factors, however, then its influence on the earning of income and wealth is very different from the pattern represented by the normal curve.

First of all, its effect when present in this combination is clearly *exponential*, not linear. That is, each additional few points of intelligence, or, better, productive ability (however that might be precisely gauged), should be expected to yield exponentially increasing results. Those of average ability, represented by IQs of 100, should be expected to earn substantially more than twice as much as morons, represented by IQs of 50. Productive geniuses who revolutionize the work of hundreds of thousands of individuals and the consumption of hundreds of millions, should be expected to earn and accumulate many thousands of times the wealth and income of the average person, which, in fact, is what they do. In connection with productive geniuses, moreover, it should be recognized how crucial is that extra measure of intelligence and ability which separates them from individuals who are merely very bright, and which gives the geniuses the ability to conceive of the new and original, not merely repeat what others have done, which is all that even the merely very bright can do.

Secondly, the very nature of productive ability in a division-of-labor society accounts for the fact that deviations from the mean value of wealth and income are not nearly so great on the negative side as they are on the positive side. This is precisely because the success of men of exceptional ability so radically increases the wealth and income of all individuals of lesser ability. Thus, while productive geniuses may earn a thousand or more times what the average individual earns, productive morons, to coin a phrase, earn many times more than one one-thousandth of what a person of average ability earns. This, as I say, is because of how much is added by the productive geniuses to the results of all individuals of lesser ability. This also helps to explain the pattern of income distribution diagrammed by Professors Samuelson and Nordhaus.⁹³

The kindest words one can say on behalf of the normal-curve argument propounded by Professors Samuelson and Nordhaus is that its supporters simply have no serious appreciation of the role of intelligence and ability in the creation of wealth. Indeed, so profound is their apparent ignorance on this score, that it suggests an alternative for what might otherwise stand as the obvious hypothesis for explaining the propounding of such an absurd doctrine. The obvious hypothesis, of course, is a readiness to grab at anything that to the unthinking appears capable of tarnishing capitalism and the success of its leading producers. But the enormous degree of

ignorance present in the normal-curve argument suggests the possibility that the deeper-lying explanation of wanting to tarnish capitalism and its producers in the first place may be simply some form of compartmentalized imbecility.⁹⁴ But whether it is a form of imbecility that causes malice against capitalism and successful individuals, or such malice that causes the imbecility, is a question that may be left to others to decide. What is important here is merely to recognize the actual relationship between inequalities of income and wealth, on the one side, and inequalities of intelligence and ability, on the other. This relationship is that inequalities of intelligence and ability operate exponentially, not linearly, in the earning of income and wealth and that the greater intelligence and ability of some is a source of gain to all.

3. The “Equality of Opportunity” Doctrine: A Critique

The advocates of economic equality have a fallback position, which they also frequently use as a camouflage, namely, the doctrine of “equality of opportunity.” They do not, they say, advocate anything so foolish or so extreme as the imposition of actual economic equality. All they advocate, they say, is that everyone have an equal chance—that, as they put it, all the runners begin the race from the same starting line. On this basis, they feel free to advocate the confiscation of inheritances, public education through the postgraduate level, and laws preventing private discrimination on the basis not only of such factors as race, religion or national origin, but also age, medical condition, and physical handicap.

The supporters of the equality-of-opportunity doctrine view opportunities as fundamentally external to the individual—in effect, as various dishes carried by waiters on trays, which, under capitalism, are arbitrarily served to some and withheld from others. They want the government to seize control, they say, not of the distribution of wealth and income, but merely of the distribution of these dishes, as it were—that is, of the opportunities to earn wealth and income—and so give everyone an equal chance.

To most people, this doctrine sounds eminently fair and reasonable. But, in fact, it is as much against the nature of reality as is the doctrine of the out-and-out equality of wealth and income. This becomes clear as soon as we look beyond the inheritance of wealth and begin to consider other external factors that affect the opportunities an individual has.

For example, consider such factors as the intelligence of a child’s parents, their education and vocabulary, their system of values, and their love for him and treatment of him, not to mention their level of income and the kind of

material life they lead and thereby expose him to while he is growing up. It is certainly arguable that differences in these factors confront a child with differences in opportunities that are certainly of no less significance for his future life, including his ability to earn wealth and income, than those which are based on the wealth he may or may not inherit.

To create equality of opportunity with respect to these factors, nothing less would be necessary than to *abolish the institution of the family and to raise all children in government orphanages, where they could all be brought up in exactly the same way*. This, of course, was the idea of Plato, and it was supported by many socialists in the nineteenth century and earlier in this century.

But even this would not be enough to achieve equality of opportunity. Because even if all of these environmental factors could be made the same, there would still remain enormous differences in the intellectual and physical endowment of the child himself, based on his genetic inheritance. A highly intelligent, strong, and beautiful child, for example, automatically has enormous advantages over a stupid, weak, and ugly child who is given the same upbringing. How can such different children, and the adults they later become, be given equality of opportunity?

One possible answer to this question is that the government should concentrate more heavily on the upbringing of the less fortunate, thus, perhaps raising their intelligence, improving their strength, and possibly even their looks. But no amount of such extra effort by the government can significantly make up for what nature has denied. Thus, another possible answer is that the government should insist that such differences simply be disregarded. The first answer manifests itself today in large-scale government support for special programs for the education of the retarded and the handicapped; the second, in those antidiscrimination laws, such as California's, which prohibit discrimination in employment based on medical condition or physical handicap.

Another possible answer is that, failing the government's ability to create equality of opportunity by raising up the less fortunate, it should tear down the more fortunate. If it cannot make the stupid intelligent, the weak strong, and the ugly beautiful, it can find a way to hamper or destroy intelligence, strength, and beauty, and so achieve equality of opportunity by making everyone stupid, weak, and ugly. It may be difficult to find anyone who would openly advocate such a policy, but it does follow logically from the goal of equality of opportunity.

There is a fourth conceivable answer: the government should attempt to determine the genetic endowment of children. It should enact a program of eugenics, and attempt to breed children who would all possess the same

characteristics at birth. Then, with the same upbringing, the demand for equality of opportunity could, apparently, at last be satisfied.

These absurd and vicious implications of the equality of opportunity doctrine should make one begin to wonder what kind of ideal "equality of opportunity" really is. In reality, it is not a legitimate ideal at all. It appears to represent justice only on the basis of a thoroughly confused view of the nature of opportunities and the causes of human success.

Let us consider what opportunities actually are, and then establish some important facts about them.

An opportunity is merely *an occasion on which successful action is possible*. It is a situation that an individual can take advantage of to his gain.

What needs to be realized about opportunities is, first of all, that *there is no scarcity of them*; they arise again and again. The second thing that needs to be understood is that what is important in connection with them and deserves to be fought for, as a matter both of justice and universal self-interest, is not that vicious absurdity "the equality of opportunity," but *the freedom of opportunity*. What the freedom of opportunity means and why it is so important will be explained shortly. Finally, what needs to be understood about opportunities is that they can be and regularly are *created* by individuals. Indeed, opportunities are themselves products of human thought and action. Just how they are is something that will also be explained shortly.

Let us consider the abundance of opportunities. An opportunity exists every time there is the possibility of improving oneself in any way. If one is penniless and there is an unfilled job available that one has the ability to fill, one has the opportunity of ending one's pennilessness. If one has a job, and there is any better job available that one has the ability to fill, one has the opportunity to improve one's position further. If there is any skill that one does not possess, but is capable of acquiring, then one has the opportunity of expanding one's skills.

In fact, in the nature of the case, the economic opportunities potentially open to the individual far exceed his ability to exploit them, with the result that he must *choose* among them, selecting some and rejecting others. This follows from the fact that there is always room for improvement in the satisfaction of man's wants, and that the basis for carrying out such improvement is the performance either of more labor or of more productive labor. In other words, built into the fact that man's wants can always be satisfied more fully or better is the opportunity for the performance of more labor as the means of satisfying them more fully or better, and the opportunity for improving the productivity of his labor.

Indeed, on the basis of what has been established

earlier in this book, in Chapter 2, it follows that in the nature of things *there are potentially limitless opportunities both for increasing employment and for raising the productivity of labor*, for there are virtually limitless possibilities for improvement in the satisfaction of man's wants. Indeed, the potential opportunities for employment always dwarf man's ability actually to work, which is a major reason why he must be concerned with raising the productivity of his labor.⁹⁵

People may wonder, of course, how it can be true that there are virtually limitless employment opportunities and yet, at the same time, the world in which we live is characterized by chronic mass unemployment and the experience of millions is that they have no opportunity for work. There is a simple reconciliation of these facts. Namely, misguided laws and social institutions deny man the freedom of exploiting the opportunities for employment that the nature of reality offers him, and so force unemployment upon him. The problem of unemployment is the result of the violation of *the freedom of opportunity*—i.e., the violation of man's freedom to exploit the opportunities that reality offers him. The freedom of opportunity means, to be precise, *the ability to exploit the opportunities afforded by reality, without being stopped by the initiation of physical force*.

People are unable to find work not because there is no work for them to do in reality, but because government and labor-union interference, based on the initiation of physical force, prices their labor beyond the reach of potential employers. This interference is, specifically, the inflation of the money supply (which sets the stage for a later financial contraction and depression) coupled with so-called prolabor legislation. The precise ways in which such interference serves to cause unemployment are explained later in this book.⁹⁶ For now, however, it may be helpful to realize that if, for example, employers have the financial ability to pay a trillion dollars a year in payrolls and there are 100 million workers able and willing to work, those payrolls would be capable of employing all those workers at an average annual wage of \$10,000 per year. But to the extent that the government and the unions keep in force an average annual wage greater than \$10,000, the payroll funds are rendered incapable of employing that many workers. The result is that corresponding unemployment is caused and can be made to continue to exist indefinitely. Thus, as this example indicates, unemployment and the lack of employment opportunity are not the result of any fundamental or "metaphysical" lack of employment opportunity, but of the government's violation of the freedom of opportunity with respect to employment. In essence, first, the government creates the boom-bust cycle, and then, when the bust comes, it and the coercive labor

unions it sanctions prohibit businessmen and wage earners from offering and accepting the lower wage rates that would enable them sufficiently to exploit the limitless employment opportunities that reality offers, to the point of establishing full employment.

As shown elsewhere in this book, the violation of freedom of opportunity is also what underlies the problems described under the head of racial discrimination. Their solution, too, would follow from the establishment of freedom of opportunity.⁹⁷

I stated that opportunities are themselves products. What I mean by this is the following. In any given instance, an opportunity is the result of a combination of external circumstances and the skills and abilities an individual possesses, such that he is able to exploit the circumstances to his advantage. An opportunity is a product in the sense that the skills and abilities an individual possesses are the result of his successful exploitation of previous, lesser opportunities.

It must be realized that opportunities are never a matter merely of external circumstances that are served up on a plate, as it were. They always depend on what the individual himself brings to the external circumstances in the way of skills and abilities. These skills and abilities in turn are never the automatic result of the individual's genetic inheritance. They are the cumulative product of what the individual has done with his life up to that point. They reflect his initial choices to use his genetic inheritance to deal with external circumstances in ways that developed certain skills and abilities, and then further choices to use those skills and abilities to deal with further external circumstances in ways that developed still further skills and abilities, and so on up to the present moment.

For example, a child who chooses to use his mind to learn arithmetic thereby creates an indispensable precondition for the potential opportunity to learn algebra. Unless and until he learns arithmetic, there can be no possibility of any opportunity for him to learn algebra. If he does learn arithmetic and then, when he is confronted with the opportunity of learning algebra, successfully exploits it too, he creates a necessary internal basis for the further opportunity of learning calculus. And so on.

It is similar with regard to employment. The individual who exploits the opportunity to become a worker in a factory thereby creates a possible basis for his later on becoming a foreman there. If he becomes a foreman, he creates a possible basis for later promotion to a higher managerial position, and so on. Of course, he will have to expand his abilities in each of these jobs and possibly acquire other skills off the job, as well—perhaps by going to night school, for example. The principle is that opportunity presents itself as the rungs of a ladder. Each

rung is open only to those who have climbed within reach by ascending previous rungs.

Once things are viewed in this light, the notion of the advocates of “equality of opportunity,” that opportunities are a matter of environmental circumstances, or environmental circumstances combined with genetic inheritance, appears absurdly inadequate. It is actually ludicrous to think that what a person does is the outcome merely of his environment and genes. In between the environment and the genes is a lifetime of choices, each of which has a vital bearing on the individual’s ability to deal with his environment and to make further choices. In between the environment and the genes is the whole life of the person as a being who functions on a level above that of an automaton.

It is not necessary that people make the choices that develop their skills and abilities at any precise moment. There is considerable leeway. And it is never completely too late to start. For example, someone can learn to read even in old age and then begin rapidly to build on that foundation.

In a free society—with its superabundance of opportunities, with no fixed deadline on the process of developing one’s skills to better exploit them—all talk of inequality of opportunity must be judged as just so much whining and excuse-making. In such a society, everyone, whatever his starting point in life, is able to raise himself very far, if that is what he chooses to do. He can miss many, many opportunities, and still there will be more. He can begin improving his ability to exploit them at any time, and start moving up from that moment.

It is true that in such a society if two individuals were born equal in every respect, except that one had richer parents than the other, and if they both actively and constantly chose to develop their skills and abilities from birth on, the one with the richer parents would probably always be ahead of the one with the poorer parents. But far from representing any kind of embarrassment to a free society, it is perfectly just that things be this way. The advantages of the individual with the richer parents would not prevent the one with the poorer parents from rising, and rising not only very high, but without any fixed limit. It is simply the case that wealth *is* beneficial, and if everything else is *in fact* the same, it makes a difference. But what else is wealth for if not to provide benefits? (And, more fundamentally, what are parents for, if not to provide every possible benefit to their children? One of the ugliest consequences of the equality-of-opportunity doctrine is that it actually causes some parents deliberately to do less for their children than they otherwise would, on the grounds that other parents are unable to do as much, and thereby willfully to default on their responsibilities as parents.) Furthermore, as ex-

plained in the discussion of the institution of inheritance, everyone, nonheirs as well as heirs, benefits from the capital that is accumulated in order to be passed on to heirs. The nonheir is thus able to achieve more than he would have in the absence of the institution of inheritance, even if that is less than what someone else can achieve who is both equally capable in every respect and has the benefit of an inheritance.

The way this principle applies in the present instance is not only that the nonheir has the benefit of a more abundant supply of products and a greater demand for his labor by virtue of the existence of capital accumulated because of the institution of inheritance, but also that he can benefit specifically in his potential capacity as a businessman and capitalist himself. In the example of the two boys who grow up with equal ability while one has the advantage of money, that advantage can enable the one without the money to make his own fortune, even if it is a smaller fortune than the one who begins with the money. For example, suppose the two of them become partners in business. If neither of them had capital, both would be equal partners, because they are equally talented. But neither of them would be able to get very far, or at least not nearly as soon, because of their lack of capital. If one of them has the necessary capital to contribute to their business, he will have more than a 50 percent share in their partnership, but the one with the smaller share will also be better off now. He will have, say, 40 percent or 30 percent of a business that now earns two, three, or five times more profits because of the capital contributed to it, with the result that his absolute share is greater. He must have more than he otherwise would have had, or he will not enter into the partnership.

Now, of course, the real fact is that individuals are not born perfectly equal in all respects but the wealth of their parents, and they do not make the same choices in connection with developing their skills and abilities. Time and again, there are individuals born to poorer parents, to parents badly deficient not only in wealth, but in education, knowledge, and even character; individuals whose own endowment at birth or in childhood is not only not exceptional, but possibly deficient in some important respects. Yet, over the course of their lives, these individuals manage to far outstrip in their accomplishments practically everyone else, despite their having begun under such seemingly insuperable disadvantages.

What enables them to do this is making the choice and the effort to exploit as far as they can whatever opportunities present themselves for self-improvement. Once they begin to do this, they actually do begin to improve themselves. And now, when they face the world, they are better equipped than before. And because they are better equipped, there are more opportunities for self-improve-

ment open to them than there were before. They seize these further opportunities, thereby further improving themselves and their subsequent ability to act and to seize opportunities. And so on, year after year.

What happens is that these individuals engage in a personal, internal process very similar to capital formation in the economy of a country. They use the means at their disposal to *build* the personal attributes—intellectual, psychological, moral, and physical—required for further success. And then they use the personal attributes they have constructed thus far to further construct such attributes. It is similar in principle to the process of a poor farmer scrimping and straining to obtain an additional supply of seed; of then using the larger supply of seed to produce a bigger crop the following year, from which a much greater supply of seed can be obtained for the year after that, and so on. Or to the economy of a whole country working very hard and saving very heavily to be able to make iron and steel available for the construction of the first railroads and steel mills, and then with the aid of those first railroads and steel mills being able to produce more of practically everything, including more and better railroads and steel mills.

Concentration on building up the means of further action, whether internal and personal or external and material, produces exponentially increasing results. Each success serves to increase the capabilities for further action, which makes possible still greater success. Those who concentrate heavily on these efforts rapidly improve, while those who neglect them stagnate or decline. It is on these principles that we can understand both such things as how Japan, so poor and backward a generation or two ago, can now be within sight of economically overtaking the United States and how Demosthenes the ancient Athenian, who began as a stutterer, could become a great orator, and how, again and again, in a free society, poor boys grow up to become rich and famous.

The secret of the success of the poor boys is contained in that old but very accurate expression that is so seldom heard today: *the self-made man*. Those poor boys *build themselves into the kind of men capable of achieving great success*. (While custom and tradition apply the principle to “boys and men,” it should go without saying that the principle applies no less to girls and women. There are self-made women, as well as men.)

The following example, perhaps, can help in understanding how by building themselves into the right kind of men they outstrip even those with the greatest advantages at birth. Thus, imagine two boys—one the newborn son of a highly educated millionaire; the other, the newborn son of a poor, uneducated coal miner. To most people, it seems that the millionaire’s son has such great advantages that he can never be overtaken. But this is not

so. And the reason why not can be seen in terms of a few conceptual snapshots, as it were, of the two boys at different stages of their development.

At birth, neither of them is capable of very much of anything. All of their capabilities remain to be developed. The millionaire’s son is not capable of jumping out of his crib and using his father’s millions to make more millions. If he is ever to have that ability, he will first have to develop it.

By age six or seven, say, the two boys have developed certain attitudes toward acquiring knowledge, and other important attributes, too, of course. But, for simplicity’s sake, we will focus just on this aspect and its possible ramifications. If the poorer boy recognizes the value of knowledge and the necessity of making his best effort to acquire it, while the richer boy does not, the poorer boy has gained an advantage that can become of growing significance over the years. By age fourteen or fifteen, perhaps, the poorer boy has acquired an important body of knowledge that the richer boy has not. He understands algebra, trigonometry, and something of physics and chemistry. The richer boy has no real understanding of these subjects. By age twenty or twenty-two, the poorer boy is capable of working as an engineer, say, and making a significant contribution to the profits of anyone who employs him. The richer boy, on the other hand can only be employed either in a menial capacity or at the expense of his father, who must continue to support him under the guise of giving him a salary, or who must provide for some associate to pay a fictitious salary, and compensate that associate in some form.

By age thirty, if he is really talented, the poorer boy has developed some significant ideas which have earned him some significant sums of money and have enabled him to start his own business. He now possesses a capacity for earning money which exceeds the richer boy’s. The richer boy may still have vastly more money and earn a larger absolute amount, but the poorer boy is in a position to earn it now at a much faster rate. For the poorer boy’s money is under his own, intelligent control and can earn a high rate of profit. The richer boy’s money is either in his own, incompetent hands, in which case he can rapidly lose it, or it is in the hands of others who are more competent but who pay him only a relatively modest rate of interest or dividends. As the years go by, with the poorer boy earning a 50, 75, or 100 percent annual rate of profit, and plowing back almost all of it, while the richer boy earns a 3, 4, or 5 percent rate of interest or dividends and consumes almost all of it, the poorer boy becomes the richer man.

This, in briefest essence, is how it actually happens that in a free society penniless newcomers are able, again and again, to overtake and surpass even those with the

greatest inherited wealth.

It cannot be stressed too strongly in this connection how critical is the element of *freedom of opportunity*. In order to succeed, the poorer boys must have the freedom to earn the highest rates of profit they can and to keep those profits. They must also be free of government controls and regulations, which can easily prevent them from ever getting started, by placing innumerable bureaucratic obstacles in their way—such as causing unnecessary delays, requiring unnecessary staffs of lawyers, accountants, and clerks that they are unable to afford, and by diverting their valuable time and efforts from serious work to contending with the arbitrary power and sheltered incompetence of government officials.

Education and the Freedom of Opportunity

Now it is also true that the success of the poorer boys depends on their being able to obtain education. But this certainly does not mean that a case is made for public education of any kind. The kind of men and boys I have described grasp very early the value of acquiring knowledge and make it their business to find opportunities for acquiring it. Public education, on the other hand, by removing all incentives of profit and loss and all possibility of genuine competition in education, and by thus sheltering inefficiency and incompetence while making improvement almost impossible, creates a system of instruction so poor that compulsion is the only means of keeping most of the students in attendance. And because people, including children, are not automatons programmed by a combination of genes and their environment, the system of forcing books and lectures on unwilling minds simply does not work.

For the kind of men and boys I have described, public education is unnecessary. What is necessary, or, more correctly, would be extremely helpful to them, and would be far more efficient and effective for everyone, is *the freedom of education*, combined with the availability of private, voluntarily supported merit scholarships and also the freedom of working and earning money to pay for education. People do not generally realize the extent to which the present system of public education destroys the freedom of opportunity with respect to education. By making educational innovations virtually impossible through government controls on curricula, faculty qualifications, and teaching methods, and requiring that competition take place against a subsidized competitor who does not charge, countless educational innovations that might have been made have not been made. People have been prohibited or prevented from exploiting the opportunities they perceive for improvement in education. The further opportunities that those improvements would have constituted for students have thus been prevented

from coming into being. We have a situation today where the law both prevents better, more economical forms of education from being offered and prevents students from earning the means of paying for education, by making it almost impossible for anyone under the age of eighteen to obtain any kind of meaningful job. Our present system is one of systematic opposition to the freedom of opportunity with respect to education.

Everyone's Interest in the Freedom of Opportunity

In general, on an increasing scale, people are prevented from exploiting the opportunities open to them, and thereby prevented from creating further opportunities that would be available not only to them but to those with whom they dealt. I have just shown how this is the case in education. On the basis of what we have seen earlier in this chapter, it is also obvious that in preventing the acquisition of fortunes, our present system prevents the opportunities from coming into being that those fortunes would have afforded to workers and suppliers in the form of a demand for labor and capital goods, and to customers, in the form of more and better products produced.

These observations bring out a further important principle pertaining to opportunities that is consistent with our wider, previous discussions both of economic inequality under capitalism and with the synergistic nature of a division-of-labor society in general, especially of private ownership of the means of production: namely, each person's successful exploitation of the opportunities open to him creates further opportunities not only for himself, but also for those with whom he deals. In other words, with respect to opportunities too, one man's gain is the gain of others. The losses caused by the violation of freedom of opportunity represent losses to everyone. This is true ranging from the consequences of aborting the earning of great fortunes and the development of major industries all the way down to the level of licensing laws aborting one man's opportunity to be a cab driver and another's opportunity to find a cab, or immigration laws aborting one person's opportunity to be a gardener or a maid and other people's opportunity of obtaining such services.

The notion of "equality of opportunity," however innocent it may sound at first, is actually vicious and absurd. In its logically consistent form, it implies the destruction of the institution of the family, the implementation of a governmental program of eugenics, and the elimination or destruction of every personal attribute that represents an advantage of one person over others.

In a positive vein, what has been shown is that what is actually important in connection with opportunities is

the establishment of a free society and its corollary *the freedom of opportunity*. In such a society, the individual is free to exploit the virtually limitless opportunities offered by the combination of his nature and the nature of the world. He must pick and choose among them. And he progressively creates better and better opportunities for himself by successfully exploiting the best of the opportunities available to him at any given time.

In such a society, the notion of equality of opportunity reveals itself as absurdly irrelevant, as nothing more than an excuse for not taking advantage of the opportunities one has and for not creating better ones. In such a society, everyone can rise no matter what his starting point or present position, and again and again people of the most humble origins overtake and surpass those who began with seemingly insuperable advantages.

What is required for everyone to be able to succeed and, at the same time, represents full justice, is not equality of opportunity, but freedom of opportunity. The successful exploitation of opportunities that freedom makes possible is the basis of each individual being able to rise and create better opportunities not only for himself, but also for those with whom he deals.

PART C

ECONOMIC COMPETITION

1. The Nature of Economic Competition

In a division-of-labor society, competition is of a radically different character than it is in the animal kingdom. In the animal kingdom, competition is over a limited, nature-given supply of means of subsistence. For the lions in the jungle, for example, there are only so many zebras or gazelles in the surrounding territory. Once the population of lions grows to stand in a sufficiently high ratio to that of the surrounding species that it eats, the individual lions are placed in competition with one another for survival. For each lion that succeeds in obtaining a supply of food, the survival of some other lion is jeopardized. For there is simply not enough to go around. In these conditions, those lions that have the keenest senses, that can run fastest and furthest, and that are the strongest, catch their prey and survive, while those that are less well endowed in these respects fail in the chase and perish. This is truly “the law of the jungle” and “the survival of the fittest.”

The competition that exists in a division-of-labor, capitalist society, on the other hand, is so radically different that it is actually of a diametrically opposite character. It is not competition over any limited, nature-given

supply of means of subsistence. On the contrary, it is a *competition in the positive creation of new and additional wealth*. Ford and General Motors, IBM and Apple, and so on, are not competing in the seizure of a fixed supply of automobiles or computers provided by nature. They are competing in the positive creation of automobiles and computers—of ever more and better automobiles and computers. While animals in the jungle chase prey, which they seize with their teeth and claws, producers under capitalism chase dollars, which they gain from willing customers only by virtue of sending after the dollars more and better goods—goods which they have created.

Man does not obtain his automobiles, computers, food, or anything else that he requires, as a gift from nature. He must produce them. His possession of reason and his organization of production into a system of division of labor enable him steadily to increase the total of the wealth he produces. Unlike the lions in the jungle, man increases the size of the animal herds that serve him (to return to that example); he domesticates them; he studies their requirements for health and nutrition and so on; he grows food for them and studies the requirements for the health and nutrition of the crops that feed them; he progressively expands and implements such knowledge, with ever increasing benefit to himself. And similarly with regard to each and every other source of his material well-being.

Economic competition takes place *within this context*—the context of unlimited potential improvement in man’s material well-being, based on his possession of reason and the organization of production into a system of division of labor. Because of this, what economic competition is about is not the means of subsistence, but, as pointed out in Chapter 5, the selection of products for markets, of technological methods for producing any particular product, and of persons for specific occupations.⁹⁸ That is, it is not at all about one human being’s survival causing another human being to perish for lack of subsistence. Rather it is about one product serving a given market instead of another product serving that market, about whether this or that technological method will be used to produce a given product, and to what extent, and about which individuals are to perform which jobs in the economic system. Throughout, it is a competition for the patronage of customers (including employers) and for the services of workers—a competition which can be won only to the degree that one renders labor more productive and so operates to raise the general standard of living by producing more and better products. Economic competition is the process of achieving an ever more efficient organization of the division of labor. It is not in opposition or in contrast to social

cooperation, as so many people have believed; on the contrary, it is precisely the process of steadily reorganizing the system of social cooperation—the division of labor—in terms of who is to produce what and by what methods, so as steadily to raise the productivity of labor and increase the quantity and quality of products produced and pouring onto the market.⁹⁹ Indeed, it is the mechanism whereby a veritable growing flood of goods is produced and poured onto the market, raising the standard of living of everyone further and further above “subsistence.”

In this competition there are no genuine, long-run losers—only winners. Everyone benefits from the ever-increasing wealth that economic competition creates. Even those who at first sight appear to be losers turn out to be winners, and usually fairly quickly. Consider, for example, the effect of the competition of the automobile on blacksmiths, horsebreeders, and buggy makers. These “losers” in this competition suffered only a very temporary loss—in the period in which it was necessary for them to adapt their skills to the requirements of other jobs. Once they did this, the only permanent effect on them of the competition they “lost” was that, along with everyone else, they too obtained the benefit of the automobile in their capacity as consumers, including, of course, the benefit of having all manner of products transported by means of trucks rather than horse-drawn wagons. In exactly the same way, the farmers using horses and mules, who lost out in competition to other farmers using tractors and harvesters, did not die of starvation, but merely ended up in different jobs. Only now, along with everyone else, they were able to obtain their food cheaper and had money left over for the purchase of larger quantities of other things—other things that could now be produced because the labor required for their production was no longer required in the production of food, thanks to the successful competition of tractors and harvesters.¹⁰⁰

It is vital to realize that there is *room for all* in the competition of a division-of-labor society.¹⁰¹ To “lose” in such competition does not mean to be cast out of the productive system and to perish. It means only to have to relocate to some other point in the productive system—to produce some different product, to work in some different occupation; or, perhaps, to continue in the same occupation and learn to produce one’s present product differently. The effect of making such adjustments is almost always that one ends up benefitting *even from the very improvement in production that caused one’s initial “loss”*—in the same way as occurred in the examples just given of the blacksmiths et al. and of the backward farmers.

The so-called weak in particular gain from the process

of economic competition. Consider all those millions who might have perished from hunger or malnutrition, or from disease or accident; who suffer from some impairment of vision or hearing; who lack the muscles or the agility to live in the jungle or the forest. And now consider the effect on them of competition among farmers and farm-equipment manufacturers; among pharmaceutical makers and manufacturers of diagnostic equipment; among the makers of eyeglasses and hearing aids; among the producers of every labor-saving device and life-enhancing product. Can anyone fail to see that such competition is what enables the weak to survive?¹⁰²

Economic competition is not a process by which the success of the biologically fit brings about the extermination of the biologically weak. On the contrary, it is the process by which the success of better products and more efficient methods of production promotes the survival and well-being of *all*. It is a process in which *the success of the more able raises the productivity and improves the standard of living of the less able*. For the competitive success of the more able is merely their achievement of positions in which *they*, rather than the less able, take charge of production. *The less able remain in the productive system and are more productive because they work under the direction of the more able*. They work in the enterprises founded and run by the more able. In those enterprises, they produce the new and improved products made possible only by virtue of the work of the more able, and they work with the aid of the progressively more productive methods of production, again, made possible only by the work of the more able. Economic competition is thus the process of improving the efficiency of social cooperation under the division of labor, and thereby of promoting the survival of every member of the human species.¹⁰³

An important aspect of the benefits of economic competition can be understood in the light of the beneficial effects that typically result from competition in such fields of human endeavor as athletics and the arts. Thus, for example, without competition, an individual can pursue such an activity merely as a pleasurable pastime, engaging in it as it suits him, with no strong dedication to improving his performance and raising it to the maximum level of which he is capable. But now let him enter into competition in his chosen activity. The immediate effect is that he is confronted with a standard that is set by the performance of his competitor or competitors. To succeed in the competition, he must exceed that standard.

It follows that for all those competitors whose performance does not presently measure up to the standard set by the leading competitor, competition creates the need to raise their level of performance—to make it exceed

the performance of the presently leading competitor. To the extent that one or more of the initially lagging competitors is inspired to surpass the initially leading competitor, the effect is to confront that individual too with a standard that he must now aspire to match and exceed. The effect of competition is thus a kind of upward ratcheting of standards accompanied by continual efforts to match and exceed the rising standards, thereby setting still higher standards, until everyone is led to exert his utmost best efforts and turn in the absolute best performance of which he is capable. In other words, competition brings out the very best in the participants.

It is the same in the economic world. Here, each company must take the quality of the goods produced by its competitors, and the prices charged by its competitors for their goods, as a standard for the quality of its own goods and for the prices it must charge. It must make its performance match and, if possible, exceed theirs. Thus, economic competition is a process by which producers are led to exert themselves to their utmost best.

Now what could be more wonderful or more beneficial than an arrangement which leads individuals to exert their very best efforts for the sake of their own and their customers' material well-being and very survival? Exactly this is what economic competition accomplishes. Exactly this is why capitalism has succeeded in so radically improving the material conditions of everyone who lives under it and in so radically lengthening life expectancy. People live and prosper under capitalism in large measure for no other reason than that economic competition drives them to put their heart and soul into doing so.

In the next section, we will consider in more detail the matter of the short-run losses that various people can experience in connection with economic competition. Following that, I will explain more fully why there is room in the competition of a division-of-labor society even for people who are less efficient than others in every respect. I will show precisely why and how even such people can have a secure place in a division-of-labor society. I will also explain further why, by the very same token, such people not only need not fear the competition of those who are more able than themselves, but derive incalculable benefits from their existence. Where appropriate, I will apply the principles derived from our discussion to the questions of international competition and free international trade. One of the major themes throughout will be that the hardships usually blamed on competition are not the result of competition, but of government intervention infringing the freedom of competition.

2. The Short-Run Loss Periods

In order to understand the problem of short-run losses and why, in a free economy, it would not be a very great one, let us consider the inherent difficulties of adjusting to the effects of competition that are experienced by three different groups of people: unskilled workers, skilled workers, and businessmen or others with invested fortunes. Between them, these groups embrace everyone directly affected.

When competition makes obsolete the job of an unskilled worker, there is no intrinsic reason for his short-run loss period to be longer than a few weeks or months. For that is the period of time required to acquire a comparable level of skill, and thus to earn a comparable level of income, in some other unskilled job. From that point on, an unskilled worker should be back to where he was in his capacity as an income earner, and he should now be in a position to benefit in his capacity as a consumer—a buyer—from the very improvement in production that displaced him.

This, of course, assumes the existence of some other job for him to take. But as explained in Chapter 2, there are always far more potential jobs out there, waiting to be done, than we are capable of doing. If the government does not intervene and so prevent the exploitation of employment opportunities that the nature of reality provides in superabundance, there will indeed be other jobs available. And in modern conditions, in which even the very poorest workers can afford the cost of a bus ride that will take them practically anywhere in the country within days, alternative employment opportunities can be drawn from the entire length and breadth of the land. The intrinsic difficulties in the way of people adjusting to the temporary job losses caused by competition are now less than ever, and diminish with every further improvement in transportation and communications.

The temporary losses suffered by skilled workers are necessarily longer lasting than those of unskilled workers. If a skill is made obsolete that required two or three years to learn, then it will probably take that much time for such a worker to acquire a comparable level of skill in some other line of work and thus, once again, to earn a comparable level of income. But even so, if the worker does reestablish his level of skill and income, then, from that point on, he too benefits from the very improvement that initially cost him his job. For he has now drawn even in his capacity as an income earner and, because of the improvement, is ahead in his capacity as a consumer. For example, a typesetter displaced by automated typesetting equipment would come out a permanent net gainer from the lower-cost books, newspapers, and magazines that that improvement made possible. He would have this

permanent net gain once he acquired a comparable level of skill and thus of income in some other line of work, perhaps two or three years later.

Now I have stressed the fact that in a free society individuals end up gaining even from the improvements that initially make them lose their jobs. It should not be forgotten, of course, that they also benefit from the overwhelmingly greater number of improvements that do not make them temporarily lose their jobs, but which purely and simply benefit them in their capacity as consumers. For example, the typesetter just referred to benefits purely and simply from the effects of competition in the production of food, housing, clothing, transportation, and everything else to which he is related merely as a consumer.

For every individual, such improvements are always in the great majority, for the simple reason that he works in only one industry at any one time, while competition affects all industries. His job is potentially threatened only by the competition which goes on within his industry, or between his industry and one or more other industries. It is not threatened by any of the competition that goes on in all the rest of the economic system—by all the competition that goes on within and between all the other industries and that does not directly relate to his one industry. Such competition merely improves his position as a consumer. In essence, if the economic system can be thought of as consisting of one-hundred industries, the individual benefits purely and simply from the effects of competition in and between the ninety-nine industries to which he is related merely as a consumer. When it comes to his own industry, he may lose his job and have to change his employment, after which he benefits in his capacity as a consumer even from the improvement that initially cost him his job.

Thus, the position of the individual in a capitalist society is that over the course of his lifetime competition improves the production and lowers the cost of practically everything, and introduces many totally new and previously unheard of products, with the result that the standard of living of the average person steadily rises. But from time to time the nature of the competition is such that the individual must change his job. At that point, his standard of living may temporarily decline. The fall in his standard of living is from an upward sloping line, so to speak; and as soon as he acquires a comparable level of skill in another type of work, his standard of living is raised to a point further up the line than it ever was before—in part, precisely because of the very improvement that displaced him.

The picture that emerges of an individual's life under capitalism, in connection with competition, is one of steady improvement punctuated by a few brief periods

of setback. The impact of such periods of setback could, of course, be minimized by the possession of savings. It could also be greatly reduced in most cases by forethought, in the form of paying attention to the factors affecting the existence of one's job and making preparations for obtaining a new job before the loss of one's present job. This would mean learning a new skill while one still had one's old job. For individuals willing to exercise such forethought, the main negative impact of competition, if, indeed, it can even still be called a negative impact, would be merely that it required them to do fresh thinking.

Indeed, in most cases, fresh thinking is practically all that competition need require of a person. For example, the great majority of the blacksmiths, horsebreeders, and buggy-makers who were displaced by the automobile did not have to wait to lose their jobs. It took over twenty years for the automobile substantially to displace the horse even in the United States, the country where the automobile made its most rapid progress. Thus most of those workers were in a position to see well in advance what they needed to do, before they lost their existing jobs. Such conditions are typical, and for many workers the impact of competition on their employment is in fact little more than that they need to learn new skills.

In a free economy, the only case of a loss period that is necessarily long and major is that of wealthy individuals who lose an invested fortune as the result of competition. The owner of a harness factory or horsebreeding farm in the early decades of this century, who lost the equivalent perhaps of a million dollars or more when his investment became obsolete, was far less likely to be able to accumulate such a sum a second time than were his workers to adapt their skills to the requirements of other jobs. For it is incomparably more difficult to earn a fortune than to learn a new job—even a highly skilled one.

Of course, even this is not impossible. There are numerous instances of individuals who have made and lost several fortunes. But for many people, especially those whose wealth has come to them through inheritance rather than their own abilities, it is simply out of the question to earn back a fortune.

Let us concentrate now on the effects of competition on this group, precisely because it is the only group whose members must probably suffer a major and prolonged loss as the result of free competition. The question we must consider is whether even the members of this group can legitimately claim to be harmed by competition.

The first thing we must realize is that the effect of competition on this group is certainly not to cause the extermination of its members, but merely their fall from

a relatively high position in the economic system to the ranks of the average. We must also keep in mind that the position of the average member of the society is steadily rising because of competition. Thus, it is only a question of time before the standard of living of a former millionaire would rise to the point where it was higher in his position as an average worker than it used to be when he was a millionaire.

This last statement is not only a theoretical inference, but also an accurate description of the actual historical facts of capitalism. The average worker in the United States today is materially far better off than a millionaire of a century ago—than even the world's very richest people of that time or of any other time much before the beginning of the present century. He has at his disposal all kinds of goods they simply did not have, such as automobiles, airplanes, electric light, indoor plumbing, radios, telephones, television sets, phonographs, tape-recorders, motion pictures, air-conditioners, refrigerators, freezers, antibiotics, modern anesthetics, and all the other advances of modern medicine. No one in the world had any of these things much before the beginning of the present century—not Queen Victoria, not Napoleon, not Louis XIV, not any of the Roman Emperors or Egyptian Pharaohs. The only respect in which these immensely wealthy individuals of the past can be described as better off than the average wage earner under capitalism today is that they had access to personal servants, which he, of course, does not. But servants to carry chamber pots and harness horses do not begin to compare to indoor plumbing and automobiles, which today's wage earner does have.

Furthermore, until about twenty-five years ago, when we still had a substantially freer economy than we do now, the rate of economic progress was sufficiently rapid so that it was not unreasonable to expect that by the time an average individual reached the end of his life, he himself would actually live better than a millionaire did when he, the average person, was a boy or a young man.

Of course, even under conditions of full capitalism, many or even most people who lose a fortune cannot live long enough for further competition and progress to give them a higher standard of living as an average person than they previously had as a millionaire. If they lose their fortune when they are sixty-five or even forty-five years old, it is virtually impossible that they will live long enough for economic progress to restore the equivalent of all that they have lost. And even if they lost their fortune, say, at age twenty-one and did perhaps live long enough, finally—say, some forty or fifty years later—to have a standard of living as an average person higher than they had had as a millionaire in their youth, the period of gain would be too short compared with the period of loss

for us to be able to say that competition had on the whole raised their standard of living in their lifetimes. Thus, even though competition and economic progress operate to raise the standard of living of the average person above that of millionaires of previous generations, they often do not do so rapidly enough to enable those who lose fortunes to improve their standard of living on net balance in their lifetimes.

Even so, there is no legitimate argument that can be raised against economic competition. Those who lose a fortune cannot logically regard competition as their enemy. For we must consider the foundation on which their fortune rested. If it was acquired legitimately, i.e., through production and trade, it could only have been so by virtue of their or their parent's or grandparent's previous success in the process of competition. To have a million dollars or more almost certainly requires that someone have earned an exceptional rate of profit that he kept plowing back over a period of years. That exceptional rate of profit represented successful competition. Thus, the fortunes that are lost because of competition were first acquired because of competition. One cannot reasonably denounce the process of competition for taking away what one could not have had without it in the first place.

This point applies in a double way. Not only is competition responsible for the existence of any fortune with which one legitimately begins, but it is also responsible for the *purchasing power* of that fortune and of every other sum of money one will ever possess. Virtually all of the products that can be bought are the result of the process of competition. The millionaire who loses the ability to buy a Rolls Royce and caviar and champagne, and who ends up having to settle for a Chevrolet and hamburgers, could not have had *any* of these things without the process of competition. To denounce competition as the source of his loss ignores the foundation of virtually everything he has or ever could have. (The same point, of course, applies to a worker who might be tempted to denounce competition for a decline in his income. The purchasing power of any income he ever earned or will earn is created by the competition of producers. There would be almost nothing for him to buy without it. And the previously higher money income he earned was itself the result of his own previously more successful competition.) Thus, an accurate description of the millionaire's loss, or anyone else's loss in connection with competition, is not to say that the phenomenon of competition has caused him any kind of actual loss or harm, but that competition both before and after his financial loss has benefitted him incalculably. It is just that after his financial loss, competition, while still benefitting him incalculably, benefits him somewhat less

than it did before, and will require some period of time to benefit him even more than it did at its previous peak of benefit to him. Always, the effect of economic competition on the standard of living of everyone is positive—enormously positive.

The Enemies of Competition as the True Advocates of the Law of the Jungle

It should be realized that it is those who denounce competition who are the true advocates of the law of the jungle. They want to preserve their or others' accustomed standard of living by means of prohibiting or restricting competition. The only way they can accomplish such a goal is by means of *the initiation of physical force*. For competitors will not stay back or stop their competition voluntarily.

For example, if the owner of a harness factory wanted to preserve his standard of living by stopping the competition of the automobile, it would not be sufficient for him merely to send a polite letter to Henry Ford explaining the hardship he was suffering on account of Ford's activities and requesting, therefore, that Ford stop or restrict his business. Ford would obviously disregard such a request, since it is overwhelmingly to his self-interest to go on with his business and increase it.

If our harness factory owner were seriously out to stop Ford's activities, the only way he could do so would be by means of force. Either he would have to employ private criminals to stop Ford, by such means as wrecking his factories and threatening his workers, or he would have to have a law passed, which would stop him by the threat of seizing his property or putting him in prison. One way or another, force would have to be his only recourse, because there is no way that Ford or any other competitor would voluntarily give up the means of making his own fortune in order to preserve the fortune of someone else. Such activity on the part of the harness-factory owner—who is in the position usually regarded as that of a victim of “the law of the jungle”—is the real law of the jungle in its human setting. For it is the attempt to live by means of force, rather than production and exchange. All those who denounce economic competition implicitly support such behavior, and in this sense are advocates of the law of the jungle.

In contrast, economic competition itself has now been clearly established as *the opposite* of the law of the jungle. It is a uniquely human mode of survival: the achievement of success by offering progressively better goods and services to others, who have alternatives for spending their money and who must be voluntarily induced to spend it in any particular way—who are induced because they are offered something better. Economic competition is both the product and the agent of man's

ongoing use of his mind to improve his life—the product of the minds of those who have something newer and better to offer, and the agent compelling all others to do the thinking necessary to be able to follow if they are to retain the voluntary patronage of their customers. It is not the law of the jungle, but of *progressing civilization*—the basis not of the survival of the biologically fittest, but of everyone, at a higher and higher level.

3. Economic Competition and Economic Security

Our discussion has important implications for the relationship between economic competition and economic security, which need to be developed.

Usually, competition is perceived as one of the foremost threats to the individual's economic security, because it can cause him to lose his present job. We are now in a position to see that in actuality *the freedom of competition is an essential basis of economic security*—that it is so in terms both of the individual's ability to obtain physical goods and services in exchange for the money income he earns and to earn a money income in the first place.

It should be realized that in its most fundamental, physical sense, economic security means the ability to obtain the goods and services on which one's life and well-being depend. It means that when one is hungry, one can obtain food, that when it is cold and raining, one has a warm, dry house to stay in; and so on. In its fundamental, physical sense, economic security obviously depends on the ability to produce. The ability to produce and physically have goods depends on the freedom of competition. The freedom of competition is thus a fundamental basis of physical economic security.

This point can be highlighted by a brief consideration of the medieval guild system, whose absurdity it makes manifest. The guilds existed in order to give their members economic security. The means chosen by the guilds for achieving economic security was the prohibition of all economic competition both by outsiders and among their own members. Thus, the bakers' guild sought security by prohibiting improvements in the production of bread; the cobblers' guild, by prohibiting improvements in the production of shoes; the tailors' guild, by prohibiting improvements in the production of clothing, and so on, industry by industry, occupation by occupation.

The effect of all this misguided seeking of security was that everyone remained much poorer and therefore much less physically secure than he needed to be. People were deprived of bread and made insecure against hunger because of the activities of the bakers' guild. They were deprived of shoes and clothing and made insecure against the elements because of the activities of the cobblers' and

tailors' guilds, and so on. And those so deprived included the members of all of the guilds. Each guild operated to perpetuate the poverty and insecurity of the whole society—that of the population standing outside the guild system, that of the members of all other guilds, and even that of its own members (for it should be recalled how people benefit even from the improvements that initially displace them). Thus, the guilds operated in a veritable self-contradiction: they professed a desire for security and yet in fact perpetuated insecurity. Much the same, of course, is true of modern-day labor unions, which are similar to the guilds in essential respects.

The focus of the guilds, to be sure, was not on the physical basis of economic security in the production and availability of goods, but on the ability of their members to have jobs and earn money income. In this respect too, their policy operated contrary to purpose, in that they themselves created the very insecurity with respect to employment and income that they feared and complained of. (Again, the same point applies to modern-day labor unions.)

The following example will demonstrate this point. Someone loses his job because competition makes it obsolete. This individual must now find a new job. This means that he must turn around and enter the labor market of some other industry or occupation *as a new competitor*. As such, what he requires is precisely *the freedom of competition*. If the whole economic system has the freedom of competition, the hardships accompanying his loss of his original job need not be very great at all. He is free to compete anywhere else in the entire economic system and will obviously pick whichever industry or occupation he feels is most advantageous for him, given his abilities, including his ability and willingness to learn. The freedom of competition also ensures the availability of an abundance of jobs. It does so because, as will be explained in detail later in this book, it makes wages, costs of production, and prices low enough so that whatever the amount of spending of money that exists in the economic system, it will be sufficient to employ everyone seeking work and to buy all that they are capable of producing.¹⁰⁴ Thus, under the full freedom of competition, the problems of finding alternative employment are minimal.

But now consider what must happen as restrictions on the freedom of competition are introduced. Now, alternative employment opportunities begin to be closed off. The consequences of losing one's present job thus become more severe. At the same time, with every further restriction of the freedom of competition, pressures are created leading to still more such restrictions. Because, with every reduction in the alternative opportunities for employment, more and more workers must crowd into the industries and occupations still open to them. In these

industries and occupations their products and services are in artificial oversupply, and their wages must suffer correspondingly. In addition, their productivity declines because an artificial scarcity exists of the complementary means of production that must be obtained from the restricted industries and occupations. To compensate for such decline in the productivity of labor, wage rates in the remaining free industries must fall still further.

Thus, as conditions grow worse in the remaining free areas, more and more of them are led to demand restrictions of their own—as a matter of self-defense. And then at last there is simply no place for an unemployed worker to go. By then almost everyone lives in mortal terror of losing his job, and opposes everything that might have that effect.

It is clear that it is largely the existence of the restrictions on competition that makes them seem so necessary. *They* are the cause of the terrifying insecurity that grips so many people at the prospect of losing their job and makes them so desperately fear competition. Competition is terrifying *when one is not allowed to compete*. People are terrified of losing the competition concerning their present jobs, because if they lose it, they are *prohibited from competing for alternative employment*. The prohibitions on their competing elsewhere are what make them cling so desperately to the jobs they have.

The belief that the freedom to compete is a threat to economic security is completely wrong. The freedom to compete is a *precondition of economic security*. The belief that it is a threat is an illusion based largely on the lack of the freedom to compete. Furthermore, it is this belief that is a real source of economic insecurity, precisely because it leads to the restriction of competition.

As a further illustration of these principles, let us return briefly to the matter of the short-run loss periods connected with competition. Hostility to competition leads to the imposition of seniority, rather than merit, as the criterion for promotion and pay increases. This artificially lengthens the short-run loss periods associated with competition. A level of skill and income that in fact should take only a few weeks or months, or, perhaps, in the case of skilled workers, two or three years, to achieve may be stretched out to ten or twenty years by the seniority system. As a result, a worker who may lose a relatively modest stake in terms of genuinely necessary experience, which he could reacquire with relatively little difficulty in another job, is made to lose a major stake in seniority, which he can reacquire only with tremendous difficulty. Such workers are obviously placed in a position in which the loss of their present jobs is made into a much worse threat than it would be under the freedom of competition and its concomitant absence of the seniority system.

4. The Law of Comparative Advantage

Now let us consider just why there is not only room but also actual *need* for everyone in the competition of a division-of-labor society, even for those who are less capable than others in every respect.

There is, first of all, the fundamental economic fact that the need and desire for goods and services are virtually unlimited, while the ability to produce goods and services is always strictly limited.¹⁰⁵ Thus, there is a need for all the productive ability that exists—even for productive ability on the most modest scale.

A good example of how the need for productive ability translates into a need for productive ability on a more modest scale is the case of a one-man business which begins to grow. Originally, the owner had time to do everything, from making all of the most important decisions to sweeping the floor. But now, as his business begins to grow, it is physically impossible for him to do all these things. It pays him to begin to employ others to do jobs which he might be better able to do than they, but which he simply lacks the time to do. Thus, even though he might be a better secretary than the secretary he employs, and better at sweeping floors than the janitor he hires, it pays him to employ these people in order to be able to carry on a larger scale of activity. Their presence enables him to concentrate on the performance of tasks in which his superiority is greater and more important, such as thinking about what needs to be done in his business.
